Since 1978, Ward has been employed at the Australian Institute of Aboriginal Studies (later AIATSIS), initially as Registrar of Sites, being responsible for the National Sites Register and assisting in the administration of the Institute's National Site Recording Program, then as Research Fellow (from 1997). He administered the Institute's national Rock Art Protection Program, acted for an extended period as Director of Research, began a series of field researches in Northern Australia, and continued to be involved with writing and editing in both Indigenous Australian and Pacific Island fields.

Ward's current research focusses on the ever-changing connection of Indigenous Australians to various landscapes. During research with Traditional Owners, in various parts of Australia, he came to view cultural heritage places, especially rock-art sites as central to Indigenous Australians' concerns. The range of related research topics extended from detailed recording and condition reporting through protection of physical fabric and the intellectual property of cultural places to matters relating to management and protection legislation (e.g., Ward 1985), the ethics of research (e.g., Cole and Ward 2000), and Indigenous Australian interests in research process and results and particularly in promoting an

Indigenous Australian voice in the discourses around rights to manage heritage places and the direction of research (Mowaljarlai et al. 1988; Ward 1992).

Over the last decade or so, Ward has continued to research Indigenous interests in cultural heritage places as they relate to perceptions of ownership and the values of tourism, aiming to establish consciousness, and evaluation, of tourism's impact on heritage places, especially rock markings, in the region centered on Wadeye (Point Keats) in the Northern Territory. Fieldwork with Traditional Owners (TOs) and staff of the Kanamkek-Yile Ngala Museum involves comprehensive recording of heritage places that are, or are intended to be, the subject of tourism and acknowledges the important role of systematic dating of sites in the perception of their cultural significances. Research aims include developing sustainable site management and educational opportunities by investigating and enhancing local control of access and impact on the sites (e.g., Ward and Crocombe 2010). With TOs and their representatives, he has made numerous presentations at conferences and symposia. Recently, his research interests have extended into aspects of visual representations beyond that of rock markings to explore similarities, symbolism, and changes in cultural significances over time (Ward and Crocombe 2008).

Major Accomplishments

In the various phases of his career, from technical studies of raw materials sourcing and the use and significances of radiocarbon dating, through field archaeology and related ethnographic studies in Australia and the Pacific, to studies of the perception of values held by, and uses made of, Indigenous Australian rock markings, Ward has worked with archaeological and other colleagues and with TOs of various heritage places. Their advocacy of protection for archaeological heritage in New Zealand contributed to the development of national legislation here. Their critical analyses of the bases of sourcing studies have been republished, and their papers evaluating analyses of radiocarbon age estimates are much quoted and provide the bases for techniques in use today. Ward's collaborations with TOs in researching into and supporting their research and conservation interests at conferences and through publications have furthered Indigenous Australians' interests in their cultural heritage places.

Ward has been a member of various professional organizations, ranging from national and state archaeological associations and committees through to areas of specific focus, such as the Australian Rock Art Research Association, serving on the executive of several associations and on the editorial boards of various journals. He has edited, or co-edited, numerous reports, collections of papers, and conference proceedings, encouraging the writing of young scholars and providing opportunities for Indigenous voices. He served as editor of the Institute's journal for several years.

In recent years, his work has focussed on the preservation and appreciation of Indigenous rock art, on educating the public as to its importance and fragility, while also assisting Indigenous communities to participate in the care and management of their cultural heritage resources.

Wari, Geography and Culture of

Patrick Ryan Williams
The Field Museum, Chicago, IL, USA

State of Knowledge and Current Debates

Wari was an expansive state that emerged in the Ayacucho Valley of Peru in the sixth century AD. At its height in the eighth and ninth centuries, it held influence over 1300 km of the Andean sierra from Cajamarca in the north to Moquegua in the south. For the first half of the twentieth century, Wari was only recognized as a northern and "coastal" variant of the Tiwanaku (Tiahuanaco) culture. The publication and discovery of the city of Huari changed that perspective, and scholars now recognize Wari and Tiwanaku as two unique and distinct contemporary, expansive polities (Tello 1970 [1931]).

Because Wari was not recognized as the center of empire until later in archaeological scholarship, researchers have both sometimes overplayed its territorial control or conversely downplayed its significance among its contemporaries. These perspectives in some cases were driven by nationalist agendas, as Wari is the Peruvian counterpart to Bolivia's Tiwanaku. In other cases, detractors of Wari's imperial role point out that its imposition of material culture on the populace is incomplete and some populations may not show overt signs of direct transformation by imperial culture.

What these detractors are forgetting, however, is that empire is the incorporation of distinct states and ethnic groups into a larger polity. Those ethnic states retain (often at imperial behest) their customs, clothing, and way of life. In most

empires, a great proportion of the populace continues living as their parents and grandparents did, though with greater exposure to both materials and ideas from other parts of the imperial realm. Wari represents an excellent case of the transformation of imperial agendas over 400 years and the changing relationships with local populations in different areas of imperial influence.

There is also a tendency to compare Wari to the later Inca empire. Many Wari scholars see the roots of Inca state institutions in Wari statecraft. Other scholars, particularly those focused on the Inca, argue that cultural borrowing and temporal transmission were not that significant in the rise of the Inca state. This relationship between ancestral nations and later states and empires is one that can be of great importance in understanding the cultural diversity in both statecraft and values in today's world. The role Wari and Tiwanaku played in the rise of Inca imperialism is undeniable, but whether earlier Wari state institutions were transformed by the Inca or Inca state institutions emerged *sui generis* is still hotly debated.

Wari scholarship is growing rapidly as the archaeological dataset that underpins our knowledge of Wari is being expanded exponentially through new excavations and new analyses on museum collections. In fact, the amount of data available from Wari settlements and collections has probably doubled in the past decade, replicating in 10 years what had taken half a century to accumulate before. And yet, there is still a great deal to explore in understanding the Wari phenomenon, which will propel our understanding of the first Andean empire in the next decades. The gaps in our knowledge and areas of growth in Wari studies are evident when we examine the antecedents and geographic extents of Wari settlement in the Andes.

Antecedents

The Ayacucho Basin was occupied in pre-Huari times by a culture known as Huarpa. Between the second and sixth centuries AD, Huarpa peoples established small villages clustered around larger towns along the 45 km length of the Ayacucho valley. They were agriculturists who used ceramics painted with black and red geometric designs on white slip. From these humble beginnings, the Wari state emerged (Lumbreras 1974). It was during the latter phases of Huarpa development that influences from the Nazca culture began to appear in the ceramic iconography, representing a cross-fertilization of ideas from the adjacent Nazca region into the highland Huarpa society.

Nazca culture flourished in the western valleys of the Andes in the drainages of the Ica, Nazca, and Acari rivers on Peru's central coast. Their towns and ceremonial centers lie just over the continental divide from the Huarpa homeland, a few days walk away. Nazca art was graphically vivid and naturalistic, with brilliantly earth tone-colored polychrome vessels. In the Nazca valley, these polychrome ceramics were produced at the civic ceremonial center of Cahuachi and distributed to the surrounding towns. The Nazca were the master craftsmen of southern Peru in the pre-Wari period, and their religious centers were likely famous throughout southern Peru, perhaps even drawing Huarpa pilgrims.

By late Huarpa times, Nazca designs and pigments began to infiltrate Huarpa iconography. This cross-fertilization formed the basis for the vibrant polychrome pottery styles that would characterize Wari state pottery production in the following centuries. In particular, Nazca designs edged with fine black outlined circles and a four-direction recurving ray icon appear in late Huarpa and early Wari styles, like Chakipampa and Ocros (Knobloch 2012).

These Huarpa innovations are accompanied by an increasingly complex settlement pattern. Huarpa communities grow in density toward the end of the sixth century AD, especially on the plateau that would become the site of Huari, capital of the regional state and later empire that bears the same name. This growth in demography is accompanied by a rapidly increasing social complexity as Wari engages with and incorporates many of the regional polities as it explodes outside its heartland and spreads across the Andes. The developments in the Wari heartland are extremely important in understanding this transition.

The Wari Heartland

The capital of the Wari polity is the site of Wari itself. Covering several square kilometers, the city housed as many as 40,000 people at its height. Major thoroughfares crisscrossed the urban center and provided access to the large rectangular compounds that formed most of the site structured the city. However, the city did grow organically unlike many of the provincial centers that were rigidly centrally planned. Irregular architecture that still conforms to the Wari courtyard house form filled in spaces in between major compounds. Elite households and administrative buildings were likely housed in the majority of these compounds within the city.

The western side of the city seems to have had a more ceremonial function according to Enrique Gonzalez Carre and Enrique Bragayrac. The D-shaped structures at Vegachayoq Moqo and Monjachayoq were likely the principle religious structures at the site, and the largest of them, set in a U-shaped mound, has been called the Templo Mayor. Moving south into Monjachayoq, subterranean cut stone galleries, some four to five stories deep, may represent the tombs of Wari's kings. And further to the southeast, William Isbell's (1991) excavations at Moraduchayoq revealed evidence for an early semisubterranean cut stone sunken court that was built over by the burgeoning urban expansion. Finally, the Cheqo Wasi sector with its stone slab tombs may have been the resting place of Wari lords.

The entire capital city was a humming metropolis with canals running through the city to supply water to the urban population and remove waste from the urban area. While the major thoroughfares provided access to the high-walled neighborhood compounds, access to areas within these districts was provided by a complex maze of passageways designed so that only the residents who lived there would be able to navigate them. The city did not contain two hallmarks of building style seen in some of the provincial centers, namely, niched halls and the blocks of geometrically organized conjoined rooms, though the latter is found at the site of Azangaro in the nearby Huanta valley north of the capital.

Azangaro, a rectangular enclosure of approximately 150 m by 400 m, is composed of three sectors. The north sector contains large Wari patio compounds, typical of administrative architecture at the capital and in many provinces. The central sector is a block of rows of conjoined rooms that may have served a storage function or perhaps housed corvee laborers. The south sector is a large enclosed space with irregular architecture within. The site, located in a lower and warmer part of the Ayacucho basin, represents a possible agricultural production center that was also tied in to Wari ritual, according to excavator Martha Anders.

Agricultural production to feed the capital city may also have been the function of the small Wari administrative site of Jargampata, located to the east of the capital (Isbell and McEwan 1991). A single patio compound, Jargampata represents a small-scale Wari administrative presence for the extraction of an important resource. Sites like Jargampata are found throughout the empire, though often they are related to larger provincial sites.

A review of Wari's heartland would not be complete without mentioning Wari's second city, Conchopata, located near the airport in the modern city of Ayacucho. Originally identified as a ceramic production center by Denise Pozzi-Escot, excavations in the late 1990s by Jose Ochatoma and Martha Cabrera (2007) revealed a dense urban settlement replete with D-shaped temples that contained the severed skulls of people from foreign lands. Located south of the capital city, Conchopata was a thriving community that produced some of the most stunning pottery in the Wari realm. Through the iconography on these pots, we see military elites, lords with chevron headbands and facial decorations, and women of noble standing as members of the community.

Wari Provinces

From its capital in the Ayacucho sierra of Peru, Wari spread its influence from Cajamarca in the north to Cuzco and Moquegua in the south. It was bounded on its southern border by colonies of the

Tiwanaku state and by local groups interacting with Tiwanaku and Wari state institutions. In the north, Wari interfaced with the Moche kingdoms vis-a-vis the highland polities with whom they had more intensive interaction and, in some instances, direct control. Such is the nature of empires, that their power and influence over vast regions are always the subject of negotiation, and that local powers weigh the benefits and deficits of affiliating with the imperial force before deciding how they will integrate or not.

The geography of Wari provincialism can be divided into northern and southern realms, which are quite distinctive in their relationships with the center. Each realm may have contained several provinces, of which four will be introduced in each the north and south. Each of the eight regions is centered on a pre-existing polity or groups of polities that had their own distinctive relationships with the Wari capital. To the north, these regions were arranged linearly along the Andean cordillera, with Cajamarca, Huaylas, Junin, and Huanca constituting the central axis. To the southeast lies the region of Cusco, and to the south were linearly arranged the regions of Parinacocha, Condesuyo, and Puquina.

In the far north, the Cajamarca region incorporates the existing polities of Cajamarca and Huamachuco that inhabited this region since pre-Wari times (Topic 1991). Peoples of these areas spoke the same language in the post-Wari era at the time of the Inca conquest (Rowe 1946). The great, unfinished administrative center of Viracochapampa lies in the geographic center of this region within the Huamachuco polity. Other Wari settlements like Huaquerones and El Palacio de Miraflores (Watanabe 2002) were located within the Cajamarca polity territory. To the west, the region interfaces with the northern Moche kingdoms in the valleys of Lambayeque, Jequetepeque, Chicama, and Moche as evidenced at such locales as San Jose de Moro (Castillo 2012). The Cajamarca region of influence is likely marked by a Wari alliance with this polity, as an interface with the northern Moche states and as a venue for extraction of resources from further north, including the rich spondylus trade-off the coast of Ecuador.

Huaylas, the second most distant of the northern regions from Wari, incorporates the headwaters of the Santa valley (the Callejon de Huaylas) and the adjacent Callejon de Conchucos. This region was inhabited by Recuay peoples in pre-Wari times and was also the heart of the earlier Chavin civilization. The Wari settlement of Honco Pampa lies at the geographic center of this region. Wari may have allied with or incorporated a Recuay polity into the imperial realm as an interface with the southern Moche state. Wari influence on the coast is most notable at Castillo de Huarmey, where a mass tomb of elite female women was discovered in recent years (Giersz and Pardo 2014), and at Chimu Capac in the Pativilca valley.

Junin, the second closest region to the north of Wari, is probably the least investigated and least known of the Wari regions in the mountainous interior that marked the heart of Wari territory to the north. But it was also the region that interfaced most closely with the pre-existing coastal Lima polities, for which recent discoveries are revealing new and exciting interactions with the Wari state. These include the discoveries of Wari elite female burials at Huaca Pucllana but also include the city of Cajamarquilla (Segura 2001) and the long known Wari contexts at Ancon and Pachacamac (Uhle 1903). The Chancay, Rimac, and Lurin valleys form the coastal zone of this region and are the source of the Wari-influenced Nievería ceramic style. The highland settlement purportedly associated with the Wari influence in this region is the site of Yanahuanca.

Huanca, the closest region to the north of Wari, is also relatively little known given its proximity to the Wari capital. Like Junin, its highland centers are on the Marañon and on the east side of the continental divide, thus not adjacent to the coastal polities. Wari Willka was perhaps its most important Wari center and shrine (Shea 1969). The coastal valleys of Mala, Cañete, Chincha, and Pisco include the settlements of Huaca Malena and Cerro del Oro, attesting to a Wari coastal presence in this region.

To the southeast lies the region of Cusco, which marks the Wari territory that interfaces with the Amazonian foothills to the east and the

high plains of the Titicaca Basin to the south. The second largest administrative center in the empire, Pikillacta, lies at the geographic center of this region (McEwan 2005). On its southern frontier, the recently identified Wari labor settlement at Raqchi marks the boundary with the Titicaca basin (Sillar 2013). The northeastern component of this region is marked by the recent finds of a Wari settlement at Espiritu Pampa (Fonseca Santa Cruz 2011), the first Wari center to be identified in the high jungle. This Wari region would become the first region of consolidation of the expanding Inca state in the early fourteenth century AD. During Wari times, local ceramic styles like Araway coexist with imperial Wari styles and mark a region of cultural ceramic production as we see in other southern Wari zones.

To the south, the region of Parinacocha marks a broad area that inhabited the highlands adjacent to the pre-Wari Nazca polities. The Wari administrative center of Jincamocco lies at the geographic center of this region (Schreiber 1992). Other rural Wari settlements in adjacent valleys such as those in Chicha-Soras (Meddens 1991) and the upper Nazca settlement of Pataraya (Edwards 2010) document an intensive occupation of the region in Wari times. As the primary interface to Nazca settlements in the Ica, Nazca, and Acari valleys, this region was likely one of the earliest areas of proto-imperial cultural development.

The second region to the south is Condesuyo, consisting of the valleys of Ocoña, Majes, Sihuas, Vitor, and their tributaries. Post-Wari peoples present here at the time of the Inca conquest included the Cabana Conde, Collagua, Alca, and Arones ethnic groups (Rowe 1946). During late Wari times, the Qosqopa style became a prevalent regional ceramic variant that linked this region together in a common material culture. The use of certain mortuary traditions, like the painted slabs that adorned Middle Horizon and later tombs, also unites the peoples of this region in a common cultural tradition. Strong Wari influence is pronounced in places like Corral Redondo in Ocoña, La Real and Beringa in Majes, Chuquibamba, and the site of Millo in Vitor.

The third and southernmost region is Puquina, named after a tributary of the Tambo valley in the region and a linguistic group that was ethnohistorically documented to inhabit the valleys of Tambo, Moquegua, Locumba, and Sama in the sixteenth century before the language disappeared a few decades later. The Puquina region has its geographic center at the Wari administrative center of Cerro Baúl. In Inca times, this region constituted the Inca province of Colesuyo. This is the only region in which Wari settlement also interfaces with Tiwanaku colonies.

Arts and Architecture

Wari provincial centers were architectural masterpieces that replicated canons found in the Wari capital and also introduced new patterns of grid planning in the distant reaches of the Wari realm. While not all Wari constructions were laid out in large blocks ahead of time, the most notable walled cities like Pikillacta and Viracochapampa followed this pattern. In both cases, urban planning of new large areas had been laid out in rectilinear districts, but the internal compounds had never been completed. This demonstrates that Wari had designs to continue to grow its provincial centers at the end of its reign that never came to fruition.

The basic building block of Wari construction is the patio group, a roughly square walled compound that enclosed a central open space (Isbell and McEwan 1991). Rooms of standardized width encircled the open patios in many cases, forming a kind of courtyard house that housed both residential and craft production activities. Walls were often plastered and painted in brilliant white colors, and floors were often plastered as well. These courtyard houses often stand two to three stories tall. Roofing was made of a thatch of ichu grass suspended on a wooden structure. While grand boulevards bisect sites like Pikillacta, small passageways connected houses within neighborhoods in the provincial centers.

In addition to the courtyard constructions, large monumental structures called niched halls graced some of the largest courtyard compounds. Present only in the administrative centers at Pikillacta and Viracochapampa, niched halls ranged in size from small 3.5 by 4 m structures

to 15 m by 42 m buildings. They are so named for the trapezoidal-based niches that are built into the walls. The rounded corners of these halls are also a deviation from the Wari norm of rectilinear architecture. John Topic suggests this architectural form may have been derived from Huamachuco constructions in the north highlands. Based on excavations in these halls, it appears they retained a religious function.

The other forms of religious architecture associated with Wari state settlements are the D-shaped temples (Cook 2001). These buildings in the form of the letter D range in size from 5 m in diameter to 20 m wide. They also contain niches in both the curved walls and along the straight-sided wall through which a door provided access to the structure. The largest D-shaped temples are located at the Wari capital, but they are present at several other important Wari centers, like Conchopata, Honco Pampa, and Cerro Baúl. D-shaped temples have yielded evidence of human trophy heads extracted from subject populations, as well as feasting vessels representing an intersection between political, military, and religious power. The feasting vessels, highly decorated ceramic forms, represent another of Wari's great artistic achievements.

Ceramic Arts

Wari innovated ceramic arts drawing on Huarpa and Nazca antecedents. They also created a culinary assemblage that introduced new forms focused on feasting and drinking. Oversized face neck jars are prevalent in both offering caches and in feasting contexts, standing over 1 m in height and capable of storing 150 or more liters of liquid. They are often highly decorated and depict a Wari lord wearing an elaborate woven tunic with facial decoration. Oversized urns are also noteworthy, especially in the assemblages at Conchopata, Pacheco, and Maymi. The Conchopata iconographic style found on some of these urns depicts the front-facing deity, a principal Wari figure, often with disembodied heads of mythical attendants. Other depictions in this style include military campaigns with warriors in their garb or symbols of plants and agricultural fecundity. Both face neck jars and oversized urns served ceremonial functions, and many were ritually smashed after limited use in feasting ceremonies (Knobloch 2012; Fig. 1).

Other serving vessels associated with the Wari drinking and feasting assemblage include keros (large beer mugs), smaller cups, and figurative vessels. Some of the keros could hold more than 2 l of liquid, though smaller cups held half a liter and were more frequent in the Wari assemblage. Bowls and serving plates are also part of the Wari decorated ceramic assemblage and come in many iconographic styles, like the Nazca-influenced Chakipampa style, the orange-slipped Ocros style, the Robles Moqo style, and the Vinaque style, all probably innovated in the Wari heartland. Other styles infused Wari ideas and icons with other ceramic traditions, like the brilliantly colored Atarco style and the coastal Nievería style. The innovation in Wari ceramics was matched or exceeded in technological sophistication by their work in textiles.

Textile Arts

Wari textiles were masterpieces of artistry and were developed in three major techniques: tapestry, tie-dye, and featherworks. Among the most exquisite of woven objects were tapestry weaves, including mantles, headbands, four cornered hats, and, most importantly, tunics. Wari tapestry is created by passing the multicolored horizontal wefts back and forth through the undyed vertical warps and packing them tightly so they conceal the warp threads underneath. The tunics were large garments worn by elite men depicting supernatural deities (the sacrificer and attendants), face frets, and less commonly anthropomorphic animals, weapons, plants, and skulls (Bergh 2012). Tunics were also created in a distinct process through tie-dye of components of woven cloth that were stitched together to form a whole. The tie-dye weaves were created by tying cloth in bundles before dying to create patterns on the fabric, often circles, diamonds, and square blocks, that were then stitched together to create patchwork patterns of brilliantly colored cloth.

Wari, Geography and Culture of, Fig.1 Extents of Wari influence and important Wari and contemporary sites in Peru

The third major area of textile artisanry was in featherwork, created from the brilliantly colored feathers of rainforest birds. The most impressive pieces are large panels or tabards, probably used as wall hangings and in some cases as interment offerings. One spectacular find in the Churunga valley of southern Peru contained 8 sets of 12 yellow- and blue-feathered panels stuffed in oversized face neck urns interred in an offering (King 2012). Feathered weaves also were used in headgear, and feathers often could adorn mummy bundles or even figures interred with them. These figurines, often made of semiprecious stone or metal, represent another area of Wari craftsmanship: a cultural fluorescence in bronze.

Metalworks and Lithic Technologies

Wari metal craftsmanship was focused on gold, silver, and copper, the latter of which was often smelted in a copper-arsenic bronze (Lechtman 2003). Wari metalwork was often focused on flashy ornaments, like large plumes that protruded from clothing or headdresses, elaborate tupus or shawl pins worn by elite women, ear ornaments, and neck ornaments like the sheet hammered silver pectorals discovered in some Wari burials. Metal masks and gold and silver plaques were also part of the decorative metals assemblage used for both adornment and offerings in Wari sites. Rare examples of metalwork include smelted copper and silver figurines found in offerings or graves at Wari sites. And while there are some examples of metal tools, like the tumi knife or metal drills, most tools were crafted of stone, the most valued of which was obsidian, or volcanic glass, mined from the volcanoes around the Wari realm.

Wari flaked stone tools and lapidary craftsmanship were also extraordinary. Obsidian, lapis lazuli, and semiprecious stones were the most valued, though local lithic material was often the

primary source for utilitarian tools. Obsidian cutting implements included laurel leaf-shaped bifaces and smaller projectile points, the most common obsidian forms found at Wari sites (Williams et al. 2012). Lapis, onyx, chrysocolla, and other semiprecious stone was shaped into beads for necklaces and bracelets as well as crafted into figurines, in some cases of mythical personages who represented founding ancestors of important lineages in the empire (Cook 1992).

The Wari arts were instrumental in tying the empire together, both through gifts to local elites as a means of purchasing their loyalty and gifts to the gods to ensure the continued productivity of the agricultural fields that supported Wari state expansion. Delivering these products around the empire required an economic infrastructure in the form of productions centers and roads. And supporting the growing state required the transformation of the landscape into more and more productive agricultural land. Thus, economic infrastructure was also a key component of Wari expansionism.

Economy and Subsistence Infrastructure

Tying together such a substantial reign required both communication networks and recording systems. The Wari developed expansive roads on which both information and goods traveled around the empire. While many of these were new trails, they also built upon existing paths that connected settlements together. Along these road systems, settlements grew up and the Wari state assisted in developing high elevation irrigation infrastructure that developed the subsistence production in regions around the empire. Finally, Wari administrative centers contained storage facilities embedded within administrative state architecture that served to maintain some of these products for state use. The Wari also invented an early form of the quipu, a set of woven cords on which numerical and categorical information could be recorded. The Wari quipu likely is the primary record keeping device of state administration.

Roads

Roads were critical to linking Wari settlements to each other and to the Wari heartland. The primary Wari roads are longitudinal networks linking similar ecological zones in the Andean valleys. As Schreiber (1992) notes, a primary ecological component of this settlement system is the location of Wari sites at the juncture between the maize-and potato-growing zones along the western flank and in the intermontane valleys of the Andes. The vast majority of major Wari sites fall within this ecological framework. Thus, Wari roads pass through this *quichua* zone (2000–3000 masl) of the Andean sierra. Wari centers also likely serve as nodes, connecting higher and lower elevation sites in the same valley to the Wari southern road network.

Wari road ecology was focused on recreating a staple reproduction strategy in each node along the network. Settlements were meant to be relatively self-sufficient in creating the means to reproduce a Wari lifestyle in these centers. Wari strived to link similar ecological niches via a road system that facilitated the movement of ideas and prestige goods. In addition to a distinctive ecological strategy of network connections, Wari invested in the infrastructure of facilities along the thoroughfares that connected capital to colony.

In many places, Wari roadways are marked with petroglyphs, indicating the trails of movement between sites in the settlement clusters. Wari investment in road infrastructure includes formal administrative centers approximately every 50–100 km along its southern trunk road, each of which is accompanied by less formal towns and villages surrounding these centers.

Trade and Exchange

Access to exotic goods acquired through long-distance exchange was an important part of social life for the Wari. Excavations indicate that Wari access to these goods was more concentrated in elite status households. Wari colonists had access

to a restricted set of luxury goods, reflecting a centralized distribution system. Obsidian is a prime example of a resource that traveled long distances to arrive in Wari sites. It is ubiquitous in Wari sites, and obsidian tools are found in greater concentrations in Wari elite residential contexts than in non-elite contexts.

Metalworks traveled long distances to arrive in Wari colonies. Within the Wari sphere in the Moquegua valley, there are copper-arsenic bronzes, copper-tin bronzes, and copper-arsenic-nickel (ternary) bronzes. These alloys represent distinct regional sources of ores from the altiplano, to the circum-altiplano, to the western cordillera of the Andes (Lechtman 2003). Moquegua is somewhat unique in that access to the ternary bronze and the tin bronze by Wari settlers is present. Other Wari colonies, like Pikillacta in the Cuzco area, are represented by a single dominant bronze source: arsenic bronzes from the western Andean cordillera (Lechtman 2003). Arsenic bronze was one of the goods that likely traveled as an interregional commodity of exchange along the Wari road system. In the provincial contexts, metal goods were widely accessible to colonial populations, especially to elite households. Exotic goods procured via long-distance exchange indicate that Wari utilized a limited number of sources but had a centralized distribution network that favored their accumulation in elite settings.

Wari focused on the long-distance movement of wealth goods, items of prestige that were easily transported but not easily replicated. Metal objects and obsidian bifaces were some of the principal commodities exchanged in this manner. Textiles were also likely a wealth medium of exchange. Meanwhile, bulk goods primarily were exchanged within regions, drawing on the area within 50–100 km of a regional center. The Wari constructed provincial nodes of production to create a more far-reaching and complex integrative system than anything before. Yet, it would not have been possible without the antecedents that Wari, Tiwanaku, and their contemporaries and predecessors developed in terms of road networks.

Agriculture

The Wari were master landscape engineers and transformed the highland Andean landscapes by constructing extensive canal systems and creating terraced irrigation agriculture. Their waterworks were especially well developed in the regions surrounding the most important provincial centers. While highland irrigation agriculture had been practiced for centuries by preceding cultures, the Wari established it on a scale not previously seen and introduced these extensive agrarian production regimes to areas where it had not previously been used (Williams 2006).

The quichua ecological zone is the primary locale of agricultural works and of Wari settlement, the staple products of which were fundamental to Wari social reproduction. These include agrarian items for local consumption in each of the Wari centers along the route. Cultigens such as maize, aji, beans, cucurbits, various cacti, and the Peruvian pepper berry, *Schinus molle*, are all grown in this zone. These same goods have been discovered in abundance in archaeological contexts at Wari sites such as Cerro Baúl.

Storage

Wari storage systems have been heavily sought and rarely extensively and definitively documented. Work in certain provincial centers has shown them to be embedded within administrative architecture, while proposals that whole sectors of sites were dedicated as storage, such as at Pikillacta and Azangaro, have been critiqued that these areas likely served as housing for corvee laborers or for other needs (i.e., McEwan 2005). At the provincial center at Cerro Baúl, storage facilities have been identified as specialized rooms within Wari patio groups (Williams 2001), in a string of square structures that formed the façade of the principal palatial residence, and in large structures flanking agricultural terracing on the slopes of the great mountain. These diverse types of storage, often embedded within other

infrastructure instead of standing alone as Inca storage structures did, have made it more difficult to identify Wari storage systems without extensive excavation in various types of architecture. As more Wari sites are subjected to intensive investigations over decades, we will likely identify more varied types of Wari state storage. Concomitant with storage, a hallmark of state administration is record keeping, a feat the Wari achieved through a relatively recently discovered class of knotted cord predecessors to the Inca quipu.

Record Keeping

Wari knotted cord records differ from their Inca corollaries in several ways. First, they often utilize wrapped pendant cords as a principal element in their construction. The wrappings around the head of each pendant cord, often decorated with geometric designs, may signal categorical information in a more explicit symbolism than the binary choices presented in Inca quipu construction. Secondly, while they do likely encode numerical information on knots in the pendant cords, the exact coding system used by Inca quipu specialists is not replicated in Wari knots, though there are some striking similarities. Knots are composed of a series of turns as they are in Inca quipus, and they seem to be organized along the cords in groups that may represent a hierarchical ordering of numbers. However, they may not use the same base ten numerical system the Inca quipu did and likely have other ways of organizing information distinct from the better studies Inca counterparts. Nevertheless, the Wari quipu demonstrates a sophisticated recording technology that laid the basis for later corded recording systems and likely worked to store and transmit information throughout the Wari realm (Conklin 1982). The transmission of information was a key facet in maintaining political network cohesion over a vast territory. It was accompanied by investment in infrastructure for the hosting of commensal events and for creating group cohesion through religious architecture that articulated a cosmological vision for the peoples of the empire.

Breweries and Commensal Politics

One way in which Wari leaders cemented relationships with each other and with local lords was through feasting events at state centers (Nash 2010). By hosting these fetes, replete with large quantities of *chicha de molle*, an alcoholic beverage made by the Wari, they were able to reinforce a common identity. In fact, recent discoveries of the Andes' oldest large-scale brewery at Cerro Baúl and the dregs of molle beer from other administrative sites indicate that brewing infrastructure was key to Wari expansion. At Cerro Baúl, a compound measuring over 400 m^2 in area contained specialized rooms for grinding grains, boiling mash, and fermenting the liquid, as well as the remains of the elaborate drinking vessels used in feasts that had been smashed on the floor of the burning buildings at the time of abandonment (Moseley et al. 2005).

The addition of *molle* berries to the corn brew is documented by the thousands of spent seeds found in pits in the floor, each with evidence that the sugary resins on the pits had been dissolved in liquid (Sayre et al. 2012). Furthermore, researchers suggest that the brewmasters were elite women based on the finds of the largest concentration at the site of elite womens' shawl pins in the brewery (Moseley et al. 2005). The beer was thus granted a special character, having been produced in specialized facilities by groups of elite women and drunk out of elaborate cups up 2 l in volume. Consumption of beer in ritual events was an important avenue of building relations among Wari subjects. But beer was not the only means of consolidating a shared identity. The Wari also established a state religion and constructed temples and religious architecture to incorporate their subjects into the empire through faith.

Religion

Wari religion, especially in later years, revolved around a figure known as the staff god or the front-facing deity. This was a creator deity,

depicted in both male and female forms and holding a staff in each hand. Attendant figures in profile accompany the central figure in some depictions, and ritually important plants and animals, like the condor, llama, puma, and maize, appear in the deity's accouterments. Wari religious iconography appeared primarily on textiles and ceramics and was likely used in ceremonies in both the public and private sphere. In many areas, Wari actors usurped preexisting shrines to make them their own. In others, they built temples in the styles of the regions they conquered to incorporate local peoples into state religion (Williams and Nash 2016). These platform and sunken court complexes in Wari's southern realm, which mimicked religious architectural forms found in the region prior to Wari expansion, were accompanied in the same sites by imperial religious architecture like D-shaped temples and niched halls. The Wari incorporated religious doctrine from the societies they encountered into their own ritual pantheon in order to make allying with Wari more attractive to competing polities. However, there is also evidence of the use of force in subjugating groups and bringing them into the Wari realm through a strong and organized military.

Military

Evidence for Wari military prowess comes primarily from iconographic representations on Wari ceramic vessels and miniature sculpture in stone and metal as well as from the skeletal remains of the victims of warfare and violence in Wari lands. Some of the most notable iconography of Wari militarism comes from an oversized ceramic urn from the site of Conchopata. Images of Wari warriors, mounted on reed boats and carrying bow and arrows or porting an axe and shield, depict the soldiers on their way to battle. Metal figurines discovered at the site of Pikillacta include warriors brandishing a sling, along with spears and a shield and a figure wielding a club over a fallen human body.

At the site of Beringa in the Majes valley, Tung (2012) documents an increase in violent trauma on human remains at the site with the incursion of the Wari state. Likewise, the trophy heads from the D-shaped temple at Conchopata have geochemical markers that indicate they were taken from peoples foreign to the Wari heartland, probably the result of conquest warfare. However, some Wari areas do not show any evidence of violence. On the Wari southern frontier, the large Tiwanaku cemeteries containing thousands of graves in the Moquegua valley have low incidences of violent trauma on the skeletal remains, and extensive implements of warfare have not been recovered in the excavations at Wari or Tiwanaku sites. Warfare was not a ubiquitous means of incorporation in Wari politics, but it is apparent that an organized military did play a role in Wari expansion and the maintenance of Wari imperialism for over 400 years. A pending question is how did the very successful system Wari established and maintained come to its end.

The End of Wari

The demise of the Wari state is still a topic that has not been extensively investigated. Some have argued the end of the Middle Horizon states was driven by climatic stress (Ortloff and Kolata 1993). Others have argued internal factionalism and contestation over hydrological resources may have been a principal factor in state collapse (Williams 2002). What we do know is that Wari administrative centers across the Andes were widely abandoned around 1000–1050 CE. In some places, ceremonial closure of state architecture, including the burning and ritual destruction of state monuments, accompanied settlement abandonment (Moseley et al. 2005).

If increasing factionalism played a role in Wari's demise, it may have been encouraged by increasing bureaucracy that impeded local leaders within the Wari realm to respond effectively to the needs of their communities and constituents. Bureaucracy is hard to measure in a society without written regulations

decipherable to today's scholars. But in some Wari centers, a vast expansion of administrative architecture appears in the latter half of Wari's existence. It is likely this expansion represents the emergence of many more state institutions, which may have been vying for more and more control over the lives of tributary communities. Disagreements over the role of community autonomy and which state institutions had authority over which communities may have created regulations which did not serve the common good but overburdened the peoples who lived in Wari towns. Eventually, this may have led to people abandoning the government and Wari way of life.

Warwasi: Geography and Culture

Janusz K. Kozłowski
Institute of Archaeology, Jagiellonian University, Krakow, Poland

Introduction

The Warwasi rockshelter is situated in the Tang-i Knisht valley near Baktharan in western Iran. In the 1950s, the site was excavated by R. Braidwood (Braidwood and Howe 1960) who made a trench of 8 × 2 m to a depth of 5.60 m, and distinguished 30 layers. The finds from these excavations are stored in the Philadelphia University Museum, and were published only in the end of twentieth century (Fig. 1).

Key Issues/Current Debates/Future Directions/Examples

The sequence of layers from Warwasi comprised Middle and Early Upper Paleolithic layers: the Middle Paleolithic layers (ZZ-JJ) represented the Zagros Mousterian (Dibble and Holdaway 1990), whereas the Upper Paleolithic layers were typical for the Baradostian, described also as the "Zagros Aurignacian" (Olszewski 1999). The review of the materials carried out by M. Otte and J.K. Kozłowski allowed to put forward a hypothesis about the continuity of the Middle and the Upper Paleolithic layers at Warwasi – since layers LL-Y display transitional features in between the Mousterian and the Baradostian (Otte and Kozłowski 2007) (Figs. 2 and 3).

The layers ascribed to the Zagros type Mousterian are characterized by Levallois technique, besides bladelet production which increase in the sequence, a stable index of side-scrapers – also shaped using the Quina retouch – increasing proportion of Upper Paleolithic tool, and a low index of denticulated-notched tools. These features are typical of other Mousterian sites in the Zagros

Mountains such as Kundji, Shanidar, Hazaar Merd, and Bisitun; also in the publications of these sites, some differences may occur that result from the subjective classification by different authors.

Layers LL-Y show the co-occurrence of Middle and Upper Paleolithic components which indicates to their transitional nature. These layers correspond to the "Early Zagros Aurignacian" (layers LL-AA) according to D. Olszewski (Olszewski and Dibble 2006). The Middle Paleolithic elements in these layers are represented mainly by side-scrapers, Mousterian points, truncated-faceted pieces, and notched-denticulated tools, also by decreasing frequency of Levalloisian technique (up to layer FF) and the presence of discoidal core technique. The Upper Paleolithic features are, first of all, bladelet production, mainly from carenoidal cores/end-scrapers. These bladelets are,

Warwasi: Geography and Culture, Fig. 2 Middle Paleolithic from Warwasi rockshelter, layer QQ: *1*, *2*, *4*, *6–8* – Mousterian points, *3* – side-scraper, *5* – truncated-faceted piece, *9*, *10* – retouched blades

frequently, with marginal retouches resembling lamelles Dufour or Arjenah points (Fig. 4).

In layers X-P the Middle Paleolithic elements vanish while blade and bladelet techniques remain. Bladelets with marginal retouches (Dufour, Krems, or Arjenah types), obtained from cores/polyhedral burins or carinated/nosed cores/end-scrapers, co-occur with blade end-scrapers and typical burins. These assemblages are typical for the Baradostian, described by D. Olszewski as the "Late Zagros Aurignacian."

The discussion around the sequence from Warwasi is related to the question of the origins of the Upper Paleolithic in southwestern Eurasia and the appearance of Modern Humans in this territory. The hypothesis about the continuity between the Zagros Mousterian and the Baradostian is either assumed to be an argument in support of the Central Asian origins of the Aurignacian (e.g., Otte 2004), or was criticized because the transitional layers in Warwasi could be nonhomogeneous. However, the recent investigations in the Yafteh Cave in Western Iran

Warwasi: Geography and Culture, Fig. 3 Transitional Middle/Upper Paleolithic from Warwasi rockshelter, layer DD: *1*, *2* – side-scrapers, *3*, *4* – Mousterian points, *5*, *6* – truncated-faceted pieces, *7* – carinated core, *8* – single platform core for bladelets, *9* – carenoidal end-scraper, *10* – dihedral burin, *11*, *12* – retouched blades, *13–19* – retouched bladelets

(Otte et al. 2007) have provided arguments in favor of continuity of the Zagros type Mousterian and the Baradostian. An argument against the post-depositional mixing up of Middle and Upper Paleolithic occupations is the considerable thickness of the "transitional layers" at Warwasi (l.5–1.8 m) and the horizontal position of these layers which makes the mixing of finds at the interface of layers fairly unlikely.

Simultaneously, the fact that Aurignacian forms occur in the Baradostian, even fairly early (in the Yafteh Cave 40–29.4 Kyr BP and in Shanidar Cave 35.4–24.5 Kyr BP), does not necessarily point to the dominating role of the Baradostian in the origins of the Aurignacian in Western Eurasia – because equally early centers – Proto-Aurignacian in nature – are registered in the Near East (Kozłowski 2010). Also

Warwasi: Geography and Culture, Fig. 4 Baradostian from Warwasi rockshelter, layer R: *1–8* – polyhedral burins/cores, *9*, *10* – end-scrapers on blades, *11* – retouched-truncated blade

questionable is the spread of the Aurignacian from Central Asia to Europe along a route that is alternative to the route via Anatolia and the Balkans, namely, to the north of the Caspian Sea, directly to the Russian Lowland (Dolukhanov 2008).

Water Buffalo: Domestication

J. S. F. Barker
School of Environmental and Rural Science, University of New England, Armidale, NSW, Australia

Basic Species Information

The genus *Bubalus* was widely distributed in Europe and Southern Asia in the Pleistocene, but later was restricted to the Indian subcontinent and Southeast Asia (Mason 1974). In historical times, the wild Asian buffalo (*Bubalus arnee*, Kerr 1792) ranged across South and Southeast Asia from Mesopotamia to Indochina. It is currently listed as endangered, with a world population fewer than 4000, potentially fewer than 200, and it is even possible that no purebred wild animals exist (http://www.iucnredlist.org/apps/redlist/details/3129/0). Domestic water buffalo (*B. bubalis*) have been classified on morphological and behavioral criteria into two types: river and swamp (MacGregor 1941). Some have referred to these as separate subspecies, naming river buffalo *B. bubalis bubalis* and swamp buffalo *B. bubalis carabanesis*. Morphologically, the swamp buffalo (Fig. 1) is gray with white chevron (one or two white stripes on the throat), socks and tip of tail, and relatively straight pale-colored horns, while the river buffalo (Fig. 2) has a black body without white markings and generally curved horns. The two types are now well known to be genetically distinct, based on chromosome number (swamp $2n = 48$, river $2n = 50$) and allozyme and microsatellite genotype frequencies (Zhang et al. 2011). Swamp buffaloes are mostly phenotypically homogenous throughout their distribution. There are no recognized breeds and they are used for draught and meat. There are a number of specialized breeds of river buffalo, however, which are primarily used for milk production. Traditional (true) mozzarella cheese, originating in Italy, is made only from river buffalo milk, and its flavor is highly prized.

Water Buffalo: Domestication, Fig. 1 Swamp buffalo (©FAO/K. Pratt)

Water Buffalo: Domestication, Fig. 2 River buffalo. (Image provided by Dr. Rakesh Kumar Pundir. (From http://www.fao.org/dadis/))

One exception to the morphological distinction of the two types is the native buffalo of Sri Lanka. Although phenotypically resembling the swamp type, they have a chromosome number of $2n = 50$ and phylogenetically cluster strongly with river-type populations (Barker et al. 1997). They likely represent the type of buffalo from which the present breeds of river buffalo were derived.

The world population in 2014 was reported (http://faostat.fao.org) as 218 million in 44 countries, although this did not distinguish between numbers of the two types. More people in the world depend on this species than on any other domestic animal species (FAO 2000). The river type is native to the Indian subcontinent, but has spread west to the Balkans, Greece, Italy, and Egypt within historical times, while the swamp type occurs throughout Southeast Asia, from Nepal, Assam, and Bangladesh in the west to the Yangtze valley of China. The geographical ranges of the two types

overlap in Eastern India (Assam) and Bangladesh and possibly also in Myanmar. The two types will hybridize, but natural mating is more successful when the animals have been raised together. First-generation hybrids ($2n = 49$) are fertile, and limited data indicate normal chromosome segregation in backcrosses and F2 animals (Cooper 1991). However, $2n = 49$ bulls in all generations show increased sperm abnormalities as compared with purebred river or swamp, suggesting reduced fertility. Some swamp buffalo populations in Australia, China, and the Philippines are being upgraded for milk production by backcrossing to river buffalo bulls.

Archaeological, anatomical, and historical evidence supports the contention that both river and swamp buffalo are descended from *B. arnee*, although the swamp type is morphologically more similar to *B. arnee* than is the river type. Recent mtDNA analysis of one *B. arnee* animal from Thailand showed ancestry to both river and swamp types, but a much closer relationship to the latter (Sarataphan et al. 2017). The time of divergence of the two types (i.e., origin of the $2n = 48$ karyotype from the putative $2n = 50$ karyotype of *B. arnee*) has been estimated in various studies as from at least 10,000 years ago to 1.7 Mya, but probably around 128,000–270,000 years ago. Even given this uncertainty, divergence occurred well before domestication (Zhang et al. 2011).

Genetic evidence clearly points to independent domestication of the two types. Cockrill (1981) stated that the river buffalo was first domesticated about 4000–5000 years ago in the riverine civilizations of the Euphrates and Tigris, and the Indus, but recent studies have concluded that the most likely area where this took place is the western region of the Indian subcontinent (Kumar et al. 2007). In contrast, the time and place of domestication of the swamp type is uncertain and subject to debate. Cockrill (1981) suggested that the swamp buffalo was domesticated in the Yangtze valley, also about 4000–5000 years ago. However, there is no evidence that the endemic distribution of *B. arnee* included Central China, and archaeological and genetic studies of Chinese buffalo do not support domestication in China. Groves (2006) noted that the oldest putative domestic buffaloes come from Neolithic sites (4500–6000 BCE) in Southern China, and archaeological findings at Ban Chiang, northeastern Thailand, show that water buffalo were already domesticated there by around 600 years BCE. Molecular genetic data (Zhang et al. 2016) indicate that the domestication center for swamp buffalo was in the China/Indochina border region. Following domestication in this region, it spread south through peninsular Malaysia to the islands of Indonesia (Sumatra, Java, and Sulawesi), north/northeast into Central China, and then through an eastern island route via Taiwan to the Philippines and Borneo.

Waterlogged Finds: Conservation

Sarah Watkins-Kenney
North Carolina Department of Cultural Resources, Raleigh, NC, USA

Introduction

Archaeological conservation is an ever-evolving discipline, which traditionally developed to preserve finds removed from their burial environment. Methods used have their roots in the nineteenth century. Today, possible conservation strategies are conservation ex situ, reburial, active conservation in situ, and passive conservation in situ. The purpose of this section is to introduce concepts, challenges, and changes in relation to conservation of waterlogged finds.

Definition

The conservation of waterlogged finds is defined as activity intended to prolong the existence of water-saturated physical remains that are archaeologically significant and undertaken with respect for the integrity of the remains.

Finds

Finds are physical remains of the past that archaeologists investigate to understand our ancestors. A find may be made of organic, inorganic, or metal materials. Organic materials are carbon based. They include animal-derived materials, for example, as leather, wool, and bone, and materials derived from plants, for example, wood and fibers. Inorganic finds are silica-based materials such as ceramics, glass, and lithics. Metals are conductive and usually highly oxidative, for example, iron, copper and tin, lead, silver and gold, and their various alloys. Finds can range from buildings and shipwrecks to grave goods, to human remains, to pieces of rubbish.

Waterlogged

Webster's dictionary defines waterlogged as "excessively saturated with. . .water." Finds in a waterlogged environment, on land or underwater, may or may not be waterlogged. The degree to which a find is waterlogged depends primarily on its porosity and hygroscopicity, which in turn can depend on its degree of degradation. Waterlogged wood is defined as having the entire pore spaces filled with water (Jordan 2001: 47; Jensen and Gregory 2006). On land, a find in a context below the water table is likely to be waterlogged. Such contexts may be in places that are natural (e.g., wetlands) or man-made (e.g., waterfronts, wells, ditches, storage pits, or graves). Underwater (as at the bottom of rivers, lakes, or the sea) a

find may be in the water column and/or buried under sediment (Gregory et al. 2012).

The effect of a particular environment on a find depends on varied and complex interactions between the material and its physical and biogeochemical environment. Characteristics defining depositional environments include water and oxygen content, hydrogen-ion concentration (pH), redox potential (Eh), presence of ion species, macro- and microbial activity, temperature, and salinity. Levels of water and oxygen are key factors determining the decay or preservation of a find. If either is limited then finds, particularly organic ones, may be well preserved. In an anoxic waterlogged environment, finds, particularly organic materials, may survive thousands of years. The presence of water, however, leads to dissolution, hydrolysis, or electrochemical corrosion depending on the material. A find may reach a state of equilibrium with the environment such that its rate of decay is minimal. Finds recovered from waterlogged burial environments may appear to be in a good condition but they may not be physically, chemically, or structurally sound (Cronyn 1990; Jordan 2001; Björdal 2012).

Conservation

Webster's dictionary defines conservation as the "act of conserving, preventing injury, decay, waste or loss" and also the "official supervision of [natural] resources in order to preserve and protect them through prudent management." Conservation of finds traditionally developed to preserve objects removed from their burial environment and to "discover the true nature of the original artifact," thereby contributing to present and future archaeological process (Cronyn 1990: 4). Conservation of finds has been described as "An operation aiming above all to prolong the life of an object by preventing, for a more or less long period of time, its natural or accidental deterioration" (Berducou 1990). Fundamental to conservation is preservation of the *integrity*, or true nature, of the object through the application of science (Clavir 1998). The integrity of a find can be cultural, scientific, aesthetic, religious, historic, and material (Kapelouzou 2012: 180).

Conservation activities, including examination, analysis, cleaning, stabilizing, repair, restoration, recording, documenting, and dissemination of information, are variously applied to gain information from finds while preventing decay and damage. International and national shared guidelines for practice and codes of ethics guide the conservation of finds as a professional discipline. Conservation is rooted in foundations of respect and uniqueness from which arise principles of minimum intervention and treatment reversibility (Kapelouzou 2012: 172–182).

Waterlogged organic finds and metals pose great challenges for conservation, organics because of their susceptibility to biodegradation and structural change, and metals to corrosion. Inorganics are, in comparison, relatively stable materials (Cronyn 1990). Challenges to conserving waterlogged finds ex situ (i.e., removed from a waterlogged environment) are deterioration due to a change in the environment, biodeterioration during wet storage, distortion due to water removal, discovery of "true identity," and long-term stability.

Historical Background

In the nineteenth century, scientific conservation of waterlogged finds began with the need to treat finds from land-based archaeology. In Denmark, from the 1830s, it was recognized that organic and metal finds recovered from waterlogged sites needed treatment to prevent their loss following recovery. Staff at the National Museum in Copenhagen quickly realized that waterlogged organic finds must be kept wet even before treatment began and that water with which wood was permeated needed to be replaced with a different material, a consolidant, in order to prevent disintegration of the find (Christensen 1970: 12–14). In 1859, it was found that boiling wood objects in alum (aluminum potassium sulfate) produced good results (Madsen et al. 2001: 37). Until 1958, alum was used at the National Museum in Denmark to conserve some 100,000 finds (Unger et al. 2001: 373). The use of alum to conserve waterlogged wood was quickly adopted in other

countries to treat large and small objects. In Norway it was used to treat parts the *Oseberg* ship, in the early 1900s (Unger et al. 2001: 374).

By the end of the nineteenth century, German and Norwegian chemists had identified the need to remove soluble chlorides from iron objects to prevent corrosion post excavation. Various treatments were developed to remove chlorides from iron by electrochemical and electrolytic reduction and heat treatments (Mardikian et al. 2010). The problems that soluble salts cause for inorganic finds, particularly ceramics, were also realized as huge numbers of finds began arriving at National Museums in Germany and Britain, from excavations of salt-rich land sites in Mediterranean and Middle Eastern countries (Watkins and Scott 2001). In the 1880s, at the Berlin Royal Museums, a chemical laboratory to research conservation treatments including desalination of ceramics, electrolytic reduction treatments for metals, and consolidation of organics was established under Friedrich Rathgen, the "Father of Archaeological Conservation" (Gilberg 1987). By the early 1920s, a research laboratory under Alexander Scott was established at the British Museum to understand deterioration and develop treatments for objects in the museum's collection. Scott was succeeded by Harold Plenderleith whose book, written with A.E.A Werner, *The Conservation of Antiquities and Works of Art: Treatment, Repair and Restoration*, published in 1956, and revised 1971, was for a long time the standard reference for treatments, including those of waterlogged finds.

From the 1950s, technological developments enabled, and increasingly expanded, access to finds underwater, including those in marine environments (Pearson 1987; Jones 2003). For these finds, conservation challenges include the removal or deactivation of soluble salts, particularly chlorides, from all materials; consolidation and drying of large organic finds, such as ships, as well as their contents; and extraction of finds from concretions. In some environments, finds are encased in concretions of calcium carbonate, shells, sand, and corrosion, within which iron finds may have completely corroded leaving voids. Discovery, excavation, and recovery of large finds, particularly ships such as *Vasa* (Sweden), *Mary Rose* (UK), the Bremen Cog (Germany), *Batavia*, and *Xantho* (Australia), during the 1960s through 1980s, led to further refinement, adaptation, and development of conservation treatments for waterlogged finds from marine environments (Pearson 1987; Jones 2003).

By the 1930s, it was already apparent that alum was not ideal (Unger et al. 2001: 382). Polyethylene glycol (PEG) as a consolidant for wood was introduced in Sweden in the early 1950s and taken up by the National Museum in Denmark following experiments in the late 1950s and early 1960s to find a treatment for five Viking-period ships (Christensen 1970). PEG has been used since to conserve most waterlogged wood finds, including *Vasa*, *Mary Rose*, and Bremen Cog. Other consolidants (e.g., ethylene glycol, glycerol, sugars, resins, silicone oils, and Kauramin), application methods (e.g., immersion, spraying), mediums (e.g., water and organic solvents), and drying methods (e.g., air-drying, freeze-drying, solvent drying) have been tried and tested (Unger et al. 2001: 363–496). The efficacy of these treatments is generally compared to that of PEG.

Mitigating the corrosion by chlorides of waterlogged metals has been a continuing quest since the nineteenth century. The problem of stabilizing copper alloys was essentially resolved in the mid-1960s with the use of benzotriazole (BTA) (Madsen 1967). No universal chloride-removal treatment, however, has yet been found for iron (Mardikian et al. 2010: 92). Early methods involved stripping off corrosion products to bare metal. Since, however, the original surface of an iron or copper alloy find is likely within the corrosion layer, following the principle of integrity requires that corrosion products as well any remaining underlying metal must be stabilized (Cronyn 1990). Research continues to characterize and understand corrosion mechanisms in order to optimize treatment methods. Treatment methods generally seek to stabilize metals by either removing, deactivating, or inhibiting the effects of chlorides. Some methods to remove chlorides involve reduction (by electrolytic,

electrochemical, or thermal means) of corrosion products to facilitate release of chloride ions. Other methods aim to inhibit their effects through control of the ambient environment to remove water and/or oxygen (Mardikian et al. 2010: 89–95).

Recovery and treatment of spectacular finds in the 1960s and 1970s led to the development of ex situ conservation methods. Through the 1990s, however, it became apparent that only a small fraction of finds in waterlogged environments, on land or underwater, could ever be excavated, let alone recovered, and treated with resources available. Instead preservation in situ – by reburial or leaving in place – has become the first, for some the preferred, conservation option rather than recovery and treatment ex situ. This approach is embodied in UNESCO's 2001 *Convention for the Protection of Underwater Cultural Heritage* (Manders 2008). With increasing pressure to leave archaeological remains in situ, conservation research and practice has expanded to include better understanding of physical and chemical aspects of burial environments as well as their effects on archaeological materials, how to monitor environments without changing them, and to determine if preservation in situ can be a reality as well as an aspiration (Corfield et al. 1997; Holden et al. 2006; Caple 2008).

Postwar urban development, in Europe and Scandinavia in the 1960s and 1970s, increasingly threatened archaeological contexts below the water table on land sites. Archaeological conservation labs were established in universities, museums, and archaeology units to treat the influx of archaeological materials, especially organic finds of wood and leather, from "rescue archaeology" preceding development in cities, including London and York in Britain and Trondheim in Norway. Since 1970, archaeological conservation has evolved as an increasingly specialized profession. Courses and programs, including B.S., M.S., and Ph.D. programs, have been established, for example, in the UK, Denmark, Canada, and the USA (Sease 1996). Unifying professional codes of practice and ethics have been agreed (Kapelouzou 2012). The development of conservation of waterlogged finds can be followed in professional journals and conference proceedings, particularly the International Institute of Conservation (IIC) journal *Studies in Conservation* (since the 1950s), journals such as *Journal of Archaeological Science* and *Journal of Cultural Heritage*, and the triennial conference proceedings of the International Council of Museums Conservation Committee (ICOM-CC) working groups for wet organic archaeological materials and for metals (since the late 1970s).

Key Issues and Current Debates

Current interests include pre- and post-conservation storage and display, effectiveness of treatment methods, retreatment, reburial, in situ preservation, and the scope of archaeological conservation (Caple 2008; Williams and Peachey 2010; Mardikian et al. 2011; Straetkvern and Williams 2012). The goal of conservation is minimal or no change to the find. This requires attaining and maintaining the find in equilibrium with its environment. Conserving a waterlogged find involves suiting the condition of the find to fit the environment or suit the environmental conditions to the find. Conservation options are conservation ex situ, reburial, active conservation in situ, or passive conservation in situ.

Conservation ex situ involves treating the find removed from its archaeological context.

Conservation can be a decades-long process, requiring researching appropriate methods and materials, gathering resources (e.g., funding, staff, facilities, materials, and equipment), and treating the finds. Finds must be kept wet until treated and dried, thus presenting problems of biodegradation of organics and corrosion of metals. Options for preventing biodegradation of organics include use of biocides, filtration, ultraviolet radiation, chilling, anoxic conditions, and high humidity (rather than immersion) (Jones 2003; Straetkvern and Williams 2012: 181–183). For metals, particularly iron, conservation options include electrolytic and/or storage in alkaline solutions (Pearson 1987; Mardikian et al. 2010: 89–95). Recently, display aquariums are being investigated to keep finds accessible and visible

for archaeologists and the public during wet storage and treatment (Björdal et al. 2009).

The ideal consolidant for the conservation of organics would be long lasting, give dimensional stability, not alter appearance, not cause shrinkage or swelling, be compatible with preservatives, allow post treatment repairs, penetrate the structure, be nontoxic, be nonflammable, resist insects and fungi, and be reversible (Unger et al. 2001: 363–364). For some projects (e.g., *Vasa*), PEG remains the best option in terms of reliability, repeatability, ease of use and economy (Hocker et al. 2012). Even so alternative consolidants are being sought that are specific to the find, either previously treated (e.g., Oseberg ship) or recently recovered (e.g., Roman ships in Italy) (Giachi et al. 2011; Christensen et al. 2012).

Conservation of iron remains an intractable problem. Research is focusing on characterizing iron corrosion post excavation to determine and clarify the role of chlorides, as well as how best to remove or deactivate them (Rimmer et al. 2012). Some projects continue with refinements of traditional treatments (e.g., electrolytic reduction and desalination via soaking in alkaline solutions). Others are experimenting with new methods, for example, the use of subcritical fluids (e.g., Mardikian et al. 2011: 39–49). Instead of removing chlorides, other projects are relying on removal of another of the agents of corrosion – water – through storage or display in very dry relative humidity to prevent corrosion (Williams and Peachey 2010: 187–200).

Reburial – following excavation, recovery and recording ex situ – allows finds to be kept in the same or similar waterlogged environment.

In an early (1985) reburial, timbers from sixteenth century Basque whaling ships were placed within a cofferdam constructed at the excavation site in Red Bay, Canada. The timbers were buried beneath sand, rock, and silt bags. Monitoring of the site in 1986, 1988, and 1992 found that an anaerobic reducing environment had been achieved; thus, preservation was presumed (Waddell 2007: 149–153).

In 2002, approximately 9,000 finds from *Fredericus* (1719) were reburied in Marstrand Harbor, Sweden, in trenches and covered by at least 50 cm of sand and clay (Gregory et al. 2012). Findings from the RAAR (Reburial and Analyses of Archaeological Remains) project, started in 2001, indicate that reburial of materials in Marstrand Harbor may be a long-term option only for large wood timbers. From examination of materials after 7 years, reburial is not recommended at all for iron, low-fired earthenware, glass, plant fiber, or horn; and up to 7 years might be considered for tanned leather, animal bone, and antler. The feasibility of longer reburial for copper alloy (bronze), medium- to high-fired ceramics, and wood is an ongoing study. Long-term survival of packing materials and labeling materials is also being tested. Polyethylene-based packing materials, graphite pencils, and permanent marker ink have survived well so far. Optimal burial depth is location specific with many contributing factors including sediment type, porosity, and organic content (Straetkvern and Williams 2012: 23–48). Continuous monitoring needs to be part of reburial strategy in line with curation of archaeological archives in repositories ex situ. Reburial removes finds from their original contexts hence the importance of cataloguing, recording, and labeling pieces.

Active conservation in situ – following excavation or survey and recording – keeps the find in its archaeological context, under active control of its condition and/or the environment to maintain equilibrium between the find and its environment.

Underwater finds, such as shipwrecks, may be physically covered, with or without their contents to provide physical protection and an anoxic environment through covering with sufficient layers of, for example, sandbags, rock, and/or devices, such as artificial sea grasses or netting, to promote sedimentation at the site (Gregory et al. 2012). In addition, rates of corrosion may be reduced through attachment of sacrificial anodes to an iron find in situ. The success of conservation in situ of large iron finds, such as vessels, cannon, and anchors, depends on monitoring through in situ corrosion measurements (MacCleod 2002: 697–714; 2005: 310–316).

On land, re-covering waterlogged finds may also involve physical covering with soil, clay,

aggregates, concrete, and/or geotextiles, to mitigate the effects of development, particularly construction work in urban sites, where finds are below the water table. Provision for continued monitoring should also be part of the mitigation strategy (Caple 2008: 216; Gregory et al. 2012). Physical protection to isolate a find does not necessarily prevent its decay – for example, the materials used may change the local chemistry at the site and/or change the hydrological conditions, with consequent deterioration of finds (Davies 2009: 56–57). Characterization of the burial environment, determination of threats (physical, chemical, biological, and/or sociological) to the find and of the condition of the find, should be made to determine measures needed to mitigate decay of the find.

Passive conservation in situ – the find may or may not be excavated, surveyed, or recorded but is left in its archaeological context – involves the natural burial environment and natural processes being relied on to maintain waterlogged conditions and to continue to preserve the find.

Relative to the number of finds that remain in waterlogged environments on land and underwater, resources are so insufficient that it is inevitable that most finds will be left, unattended or modified, in situ, where, it is hoped, the environment remains unchanged and will not present a physical, chemical, or biological threat to them (Manders 2008). Unfortunately, as more investigation and monitoring are done, it is clear that no change to a burial environment or the archaeological remains within can be guaranteed.

Research in Scandinavia and England suggests that the corrosion rate of iron and copper alloys still in the ground is increasing due to air pollution, climate, and hydrological changes. In England, all ancient monuments in 1945 contained an estimated four billion iron and copper objects. Over 50 years to 1995, an estimated 14 million were lost per year due to site loss or damage, with an additional 5 million lost due to corrosion. (Caple 2008: 215). For waterlogged land sites, not only is maintenance of groundwater levels crucial but also its level of contamination and degree of oxygenation. Hydrological changes at a site may be a consequence of changes in land use, climate change, and sea-level change occurring many miles from the site (Davies 2009: 15–16). For effective preservation in situ, monitoring of a site within its environment, not just of the environment of the site, is essential (Holden et al. 2006: 61).

Underwater, environments presumed to provide preservation of finds are also changing with consequent acceleration of decay of finds. For example, wood-destroying shipworms are appearing in the deep cold waters of the Baltic Sea (Straetkvern and Williams 2012: 9–14). "Preservation in situ" is potentially misleading since research indicates that while finds remain buried, not all are being preserved – the rate of decay may simply be slower than it might be if they were at the surface (Caple 2008: 215). Continuing corrosion and decay of large iron shipwrecks, such as USS *Arizona*, may lead to collapse of hulls, loss of remains, disturbance of grave sites, and pollution (e.g., release of fuel) (Mardikian et al. 2011: 400–408).

Changing the Scope and Concept of Archaeological Conservation?

Archaeological conservation traditionally developed to preserve finds removed from their burial environment. To prolong the integrity of finds, conservators sought to attain a situation of minimal or no change (Cronyn 1990; Kapelouzou 2012). Since the 1990s, preservation in situ and reburial have increasingly become alternative conservation options to recovery and treatment ex situ. Research and observation, however, indicate that neither leaving nor reburying finds in a waterlogged environment prevents change in condition.

Most training courses for archaeological conservators focus on treatment of individual objects and care of museum collections. Should the remit and scope of archaeological conservators now be extended to include preservation of finds in situ? Should conservation education and training expand to include additional knowledge and associated skills (e.g., in hydrology, geological sciences, engineering, land management) with

understanding and awareness of moral judgments concerning economic impacts of changing land use, the effects of natural habitats on wildlife, and ethical implications of taking actions to preserve objects which cannot be seen (Caple 2008: 216).

Such an expansion of scope also raises the question of reexamining concepts that have defined archaeological conservation since the 1970s, including to what extent can principles developed for conservation of finds ex situ be applicable for finds in situ? To what degree is it possible, or reasonable, to control change of the environment and or the find if it is left in situ? Does prolonging the existence of an object necessarily mean no change? For how long is a find's existence to be prolonged? Does the definition of archaeological conservation need to be altered to embrace the inevitability of change? For example, English Heritage's definition of conservation of the historic environment; "the process of managing change to a significant place in its setting in ways that will best sustain its heritage values, while recognizing opportunities to reveal or reinforce those values for present and future generations" (English Heritage 2008: 7).

International Perspectives

Since the establishment of the ICOM-CC working groups for wet organic archaeological materials and metals in the mid-1970s, conservation of waterlogged finds has become an international practice. For example, by the mid-1980s, over 450 papers and reports from 30 countries on waterlogged wood had been published (Jones 2003: 6). The published proceedings include transcripts of discussions that provide additional insight into issues, debate, and controversy over the years. The evolution of conservation research and practice can be followed, in which projects increasingly involve collaborators from different countries. Current international perspectives on conservation of waterlogged finds appear in the 2010 conference proceedings for ICOM-CC WOAM and are summarized below (Straetkvern and Williams 2012) and for ICOM-CC Metals (Mardikian et al. 2011).

Researchers in various countries collaborate to undertake and contribute to the conservation of waterlogged finds from land and underwater sites, including research into new conservation materials and methods, assessing effectiveness of traditional treatments, and contributing expertise and experience gained to other nation's projects. For example, conservators from Norway, Sweden, and Denmark are investigating retreatment of alum-consolidated wood, including the *Oseberg* ship. Investigations and research to understand and improve the condition of *Vasa*, in Sweden, include researchers from Denmark (National Museum), the United Kingdom (Mary Rose Trust), the USA (Texas A&M), and Australia (Western Australian Museum). Relatively new projects started since the 1990s may include advisory panels drawing on international expertise – for example, the Newport Ship (Wales), in the USA *Hunley* and *Monitor* conservation projects, and the Yenikapi ships in Turkey.

The search for the ideal consolidant for waterlogged wood continues at centers in several countries; for example, in France (Arc-Nucleart in Grenoble) and Australia (Western Australian Museum, WAM), testing use of azelaic acid; in Japan (Toyo Feather Industry Co. Ltd., and Kyoto University) and Australia (WAM), use of feather-derived keratin; and in Canada (Canadian Conservation Institute, CCI), different types of PEG, and in the USA, Texas A&M has pioneered the use of alkoxysilanes or silicone oils. The presence of sulfur and/or of iron in wood affects the penetration of consolidants and their long-term stability. Researchers in Australia (WAM) and Sweden are seeking to improve wood consolidation by researching methods to remove iron from wood. Extraction of sulfur from wood is being investigated in France (Arc-Nucleart). In England, the Mary Rose Trust and University of Canterbury as a treatment method for Mary Rose timbers are researching sulfur deacidification with nanoparticles of strontium carbonate (Straetkvern and Williams 2012: 419–424).

Removal or deactivation of chlorides in iron finds continues as a research focus in the UK and

the USA. At Cardiff University, Wales, conservators and scientists have been researching and evaluating methods of chloride extraction for over 30 years. Collaborative research projects now include conservators at the British Museum and English Heritage. In the USA, conservators and scientists at the Warren Lasch Conservation Lab and Clemson University are investigating stabilization options for *Hunley* submarine hull, including use of subcritical drying fluids.

International collaborative projects are investigating aspects of preservation in situ –including characterizing burial environments, understanding the decay of materials, and mitigation strategies to inhibit change, in waterlogged environments on land and underwater. The RAAR project, based in Sweden, includes researchers from Denmark (National Museum) and Australia (WAM). Scientists and conservators at WAM pioneered in situ corrosion monitoring and use of sacrificial anodes, for conservation management of iron ships and artifacts still underwater, and provided advice and expertise to projects worldwide (MacCleod 2002: 697–714; 2005: 310–316).

Future Directions

Conservation is an ever-evolving discipline. As examination techniques and available expertise improve, particularly in understanding the evidence that may be preserved and retrievable, conservators are better able to understand the short- and long-term effects of treatments. Feedback from dissemination of findings and constant review, particularly as conservation research deepens understanding of how materials deteriorate in different environments and effects and effectiveness of treatments, should lead to continuous evaluation and reassessment of methods and treatments used.

Conservation of archaeological finds traditionally developed to preserve finds removed from their burial environment. Research needs to continue to improve old methods and develop new methods for treatment of finds ex situ. Since the 1990s, preservation in situ and reburial have become alternative options to treatment ex situ. Preservation in situ is still a nascent discipline; more work is needed to ensure this option combines understanding of the environment, the find and processes of deteriorations, with a commitment to continuous monitoring (Gregory et al. 2012). With increasing single-site data and multi-site data synthesis, prediction modeling may help inform decisions as to the best conservation option for a particular find, whether to conserve ex situ or in situ. Technological advances for imaging sites and finds are not only providing opportunity to better record and share information about finds and their condition but may also provide another conservation option – that of virtual conservation. A find may or may not be recovered, but it is recorded such that it continues to have a "virtual" existence, even if its remains are abandoned, discarded, and lost. In deciding future options for conserving waterlogged finds, it needs to be determined whether maintaining constant condition or managing change is the ultimate goal. If the definition of archaeological conservation is altered, underlying principles including those of reversibility and minimum intervention may also need to be reframed.

Conservation has become a profession guided by unifying codes of practice and ethics (Kapelouzou 2012). Conservation of waterlogged finds, however, is not an activity that can be done in isolation – conservators are part of the archaeological process and have a key role in the archaeological team. Understanding and mitigating the effects of environments on finds – whether in the burial or museum environment – is increasingly a multidisciplinary exercise, including expertise from, for example, the geological, biological, and social sciences. The decision to conserve a waterlogged find requires not only an archaeological commitment but also social and political ones. Commitment of resources in the present and long term will be needed. Whichever conservation option is chosen to prolong the existence of finds *for* present and future generations, its achievement will require commitment *by* present and future generations.

Watkins, Joe (Indigenous Archaeology)

Ian Thompson
Historic Preservation Department, Choctaw Nation of Oklahoma, Durant, OK, USA

Basic Biographical Information

Joe Watkins (1951–), a member of the Choctaw Nation of Oklahoma, is a tireless worker in the development of indigenous archaeology, who, for three decades, has broken new ground in conducting collaborative work with indigenous communities, in encouraging indigenous persons to enter the field of archaeology and in promoting self-reflexivity within the discipline toward its relationships with descendant communities.

Joe E. Watkins was born February 18 at Talihina Indian Hospital to Irving and Thelma

Watkins. He is a nephew of Joseph Oklahombi, a Choctaw Code Talker and World War I hero. Growing up, Joe learned Choctaw traditional philosophy and culture during stays with his Choctaw-speaking grandparents in southeastern Oklahoma and was encouraged by them to respect and preserve indigenous history. He received a B.A. in anthropology from the University of Oklahoma in 1973, cultivating an interest in material culture. The same year, Joe went to France to study morphological typology and flintknapping with Francois Bordes. Soon he developed a tremendous artistic talent, not only in flintknapping but also in carving, beadwork, and featherwork. In 1977, Watkins received an M.A. in anthropology with an archaeology specialization from Southern Methodist University (SMU). He then completed fieldwork in experimental archaeology for a doctoral dissertation, only to have it rejected before defense.

During the turbulence between Native Americans and archaeologists in the 1970s, Joe found himself in occasional internal conflict, but also in a unique position for understanding both groups' viewpoints. In the late 1970s and 1980s, he drew upon this perspective to serve as a representative to the American Indian Religious Freedom Act Task Force, as an archaeologist/Native American specialist for the Department of the Interior, and as an archaeologist for the Oklahoma Archaeological Survey, where he completed more than 300 projects. Joe and his (then) wife Isabella Peralta-Romas were blessed with two children, Ethan in 1991 and Sydney in 1992. In 1993, he participated in a workshop sponsored jointly by the Society for American Archaeology (SAA) and the National Science Foundation, which led to the formation of the Principles of Archaeological Ethics. Joe conducted a second dissertation project at SMU, analyzing archaeologists' responses to questions about interaction with Native Americans, and, in 1994, became one of the first Native American archaeologists to attain a Ph.D. His dissertation (Watkins 2001), one of the seminal works in indigenous archaeology, closes with the insight: "That is what indigenous archaeology can bring to the discipline: a viewpoint that refuses to be 'objective' and embraces the emotional, one that pursues not "truth" but understanding, and one that includes all facets of what it is to be human on the brink of an exciting adventure" (Watkins 2001: 181).

Dr. Watkins worked as an archaeologist for the Bureau of Indian Affairs Anadarko Agency from 1993 to 2003, concurrently serving as an instructor at the University of Oklahoma, Indiana University, the University of Nevada-Reno, and Flinders University, Australia, teaching courses on archaeological ethnics and Native American consultation. He also began serving as a consulting archaeologist for the Choctaw Nation. He received the SAA Presidential Award in 1997 and again in 1999 and the Oklahoma State Historic Preservation Officer's Citation of Merit in 1999. During this period, Dr. Watkins chaired the Committee on Native American Issues for the Register of Professional Archaeologists and the Committee on Ethics for the American Anthropological Association, as well as the Committee on Native American Relations and the Native American Scholarships Committee for the SAA. In 2001, he co-organized a conference at Dartmouth College that explored the relationship between Native Americans and archaeologists; out of this came the "Closet Chickens," a networking and support group for Indigenous archaeologists. From 2003 to 2007, Dr. Watkins served as an Associate Professor in the Department of Anthropology at the University of New Mexico. In March 2006, Joe Watkins married Carol Ellick: archaeologist and illustrator. In 2007, he accepted directorship of the Native American Studies (NAS) Program at the University of Oklahoma, where he was instrumental in setting up both a NAS masters program and a program to train Tribal Historic Preservation Officers. An indefatigable worker, Watkins has authored 3 books, 55 articles, 30 book chapters, and 20 scholarly reviews, over the last 17 years, principally concerning Indigenous archaeology and archaeological ethics. He has also given nearly 200 professional presentations and has served on nearly 3 dozen boards and committees. Currently, he serves on the Choctaw Nation NAGPRA Advisory Board, is a member of the Indigenous

Advisory Committee of the World Archaeological Congress, and chairs the SAA Committee on Ethics in Archaeology. Recent research involves collaboration with Ainu communities in Japan and the Beswick and Barunga communities of the Northern Territory in Australia.

Major Accomplishments

Joe Watkins' professional work and personality contributed to the formulation of Indigenous archaeology and continue to influence its development to this day. Through the turbulent 1970s to 1990s, he maintained a humanistic approach, advocating respect, communication, and understanding between the Native American and archaeological communities. As Indigenous archaeology has matured, he has helped to shift the dialogue from a focus on repatriation to broader issues of maintaining cultural continuance and communication and making long-term commitments for increasing the relevance of archaeology (e.g., Watkins 2010a, b). Through his prolific writing and presentations, his work on many boards and panels, and his university teaching, he has a broad and lasting influence on upcoming generations of archaeologists, indigenous and nonindigenous alike (e.g., Watkins and Ellick 2011).

Watkins, Joe (Theory)

George P. Nicholas
Department of Archaeology, Simon Fraser University, Burnaby, BC, Canada

Basic Biographical Information

Joe Edward Watkins (Fig. 1) is an American archaeologist and anthropologist and a member of the Choctaw Nation of Oklahoma. In 2013 he was supervisory cultural anthropologist and chief, Tribal Relations and American Cultures program for the National Park Service (NPS), an opportunity that allows him to develop more effective and satisfying relationships between this organization and communities. In 2014 he took on the role of American Indian Liaison for the NPS. He served in all three positions until his retirement from the NPS in 2018.

Watkins received his B.A. in anthropology from the University of Oklahoma and both his M.A. (1977) and Ph.D. (1994) from Southern

Watkins, Joe (Theory), Fig. 1 Joe Watkins. (Photo by Carol J. Ellick)

Methodist University. After completing his M.A. degree, he held the position of archaeologist/Native American specialist for the Heritage Conservation and Recreation Service of the US Department of the Interior, in Atlanta (1978–1980). This led to several years running his own CRM company, American Indian Cultural Consultants, Inc, in Oklahoma. Following that, he served as archaeologist/environmental coordinator for the Branch of Land Operations, US Department of the Interior, Bureau of Indian Affairs, in Anadarko, Oklahoma (1993–2003). Watkins was also assistant director of the Oklahoma Indian Legal Services (1982–1984); business manager of the Millicent Rogers Museum in Taos, New Mexico (1984–1987); and archaeologist for the Oklahoma Archaeological Survey (1990–1993). He was associate professor of Anthropology at the University of New Mexico from 2003 to 2007. He was then director of Native American studies at the University of Oklahoma, Norman (2007–2013), where he taught courses on indigenous archaeology, tribal historic preservation, and contemporary issues in Native American studies.

Watkins' interest in archaeology developed when, as a 10-year-old, he discovered a projectile point near his grandmother's homestead, which led to an early lesson in the complexities of cultural heritage from his grandmother who told him that the artifact related to someone else's past, not his, since the Choctaw had been relocated to Oklahoma from Mississippi in the 1830s. Addressing challenges relating to the legacy of colonialism would become an underlying theme dominating Watkins' career. During the early part of his academic life, inspired by the archaic point, his interests focused on material culture, lithic analysis, and experimental archaeology. In 1972, he spent time in France working with Francois Bordes at the site of Pech de L'Aze IV, where he learned flintknapping and Bordes' classification system from the master himself and also worked with Jacques Tixier and Bruce Bradley. In 1975, he built a full-sized late prehistoric-style, subterranean, earth-covered pit house at the Fort Burgwin Research Center near Taos, New Mexico, which he lived in throughout the winter and engaged in a variety of traditional activities – from corn grinding and food preparation to pottery and basket manufacture to flintknapping, arrow making, and hide-working – to gain insight into the lifeways of ancient Southwesterners.

As a young Native American scholar, Watkins found himself increasingly questioned by archaeologists as to his objectivity and by indigenous community members as to his "Indianness." Such encounters contributed to his interest in European and later sub-Saharan African archaeology, which afforded the opportunity to avoid having his credibility and integrity questioned. However, Watkins' reentry into North American archaeology came about through his post-M.A. foray into the legislative side of archaeological heritage through a position he held with the Heritage Conservation and Recreation Service of the US Department of the Interior. He participated in a series of national consultations on the American Indian Religious Freedom Act of 1978 and the impact of the federal policies on tribal communities that sought input from community members. These consultations brought forward many perspectives on the effects of archaeological and heritage management practices upon sacred sites, access to sacred objects, and human remains and cemeteries. Deeply affected by the testimonials he witnessed, his interests subsequently shifted to the ethical practice of anthropology and the study of anthropology's relationships with descendant communities and aboriginal populations, topics that have dominated his career ever since.

Major Accomplishments

Over the course of more than 50 years, Watkins' research and writing have spanned the realm of archaeology, from culture history to processual and postprocessual archaeologies, with significant contributions to each, in addition to more than 25 years' involvement in cultural resource management. His interests include the history and application of heritage legislation in the United States and elsewhere; CRM policy and practice; archaeological ethics; plains archaeology; public archaeology; lithic technology, experimental

archaeology, and material culture studies; Native American studies; indigenous archaeology; education; identity and nationalism; and intellectual property.

Watkins' most recognized and valued work is focused on the dynamic and multifaceted relations between indigenous communities and the discipline of archaeology. His dissertation – Ethics and Value Conflicts: Analysis of Archeologists' Responses to Questionnaire Scenarios Concerning the Relationship between American Indians and Archeologists (1994) – provided a critical review of the controversies surrounding the Kennewick Man/Ancient One, the Wenatchee Clovis Cache, and other cases. This work was later revised and published as *Indigenous Archaeology: American Indian Values and Scientific Practice* (Watkins 2000), which is today the most widely cited title in the realm of indigenous archaeology.

In 1993, Watkins participated in the joint Society for American Archaeology/National Science Foundation-sponsored workshop that led to the formulation of the Society for American Archaeology's Principles of Archaeological Ethics (and he continues to press for review and revision). He has also been very active in the American Anthropological Association; in addition to other AAA roles, he was a member of their "Darkness in El Dorado" Task Force in 2002, charged with the difficult task of assessing charges brought against James Neel and Napoleon Chagnon by journalist James Tierney. He was an advisor to the MATRIXX (Making Archaeology Teaching Relevant in the XXI Century) project, sponsored by the SAA Task Force on Curriculum. Since 2009, Watkins has been a member of Time Team America, an archaeology/reality television program produced by the (US) Public Broadcasting System. He was also a steering committee member of the Intellectual Property Issues in Cultural Heritage (IPinCH) Project (20108–2016).

Watkins is an accomplished educator and administrator, with an outstanding record of advisory board, committee chair or member, and executive service for such state, national, and international organizations as the Alfonso Ortiz Center for Intercultural Studies, American Anthropological Association, National Museum of Natural History, Oklahoma Council for Archaeological Preservation, Plains Anthropological Society, Register of Professional Archaeologists, Society for American Archaeology, Society of Professional Archaeologists, University of Oklahoma, Wenner-Gren Foundation, and World Archaeological Congress. He has been a Fulbright scholar and a Ford Foundation fellow, has received a Citation of Merit from the Oklahoma State Historic Preservation Office, and has been twice awarded a Presidential Recognition Award by the Society for American Archaeology. Watkins was elected to serve President-elect of the Society for American Archaeology (2018–2019) and President (2019–2021).

Watkins' contributions to archaeology and anthropology have been substantial, as they have also been to indigenous communities in North America and beyond. His integration of indigenous, anthropological, and historical perspectives reveals similarities and differences in the experiences of Native Americans and other colonized, marginalized, and underrepresented populations. Such efforts have also provided important insights into the impacts archaeology has had on indigenous peoples and vice versa. He has also worked with aboriginal groups in Australia and is currently involved with indigenous Ainu communities in Japan to compare their struggle with that of American Indians in historical, political, social, cultural, and economic spheres.

As an archaeologist and a Choctaw, Watkins straddles two different worlds and ways of knowing – one based on Western scientific tradition and the other on traditional knowledge – each with often very different needs, goals, values, and demands. At the intersection, he has worked to promote ethically sound and mutually satisfying archaeological practices, a desire likely instilled by that lesson on heritage provided to him by his Choctaw-speaking grandmother when he was young. As a Native American scholar who has experienced formidable challenges in his career, and whose work has always promoted relevance and responsibility in archaeological practice, Joe Watkins serves as an important role model not only for aboriginal

youth but also for established scholars of any background.

Watson, Patty Jo

George M. Crothers
Anthropology, University of Kentucky, Lexington, KY, USA

Basic Biographical Information

Patty Jo Watson (Fig. 1) is an American archaeologist whose theoretical writing was instrumental in the development of an explicitly scientific archaeology. Her research interest focused on agricultural origins in western Asia and eastern North America. Born in 1932 in Superior, Nebraska, she grew up in rural Nebraska and Iowa before attending the University of Chicago in the 1950s. She received an M.A. in anthropology in 1956 and a Ph.D. in 1959 working under the direction of Robert Braidwood, a pioneer of modern archaeology.

Watson, Patty Jo, Fig. 1 Patty Jo Watson

Watson's first field training was at the University of Arizona Point of Pines Field School in 1953. In 1954–1955, she was a field assistant on Braidwood's Iraq-Jarmo Project, an important multidisciplinary project to investigate the origins of agriculture in the Hilly Flanks of the Zagros Mountains, northern Iraq. This model of problem-oriented, interdisciplinary research was championed by Watson throughout her career. In addition to research in Iraq and Iran, Watson conducted major fieldwork in Turkey, New Mexico, and Kentucky in collaboration with colleagues and students, including her husband, Richard Watson, a philosopher of science and a geologist.

In the 1960s, Watson taught at Los Angeles State College, University of Southern California, University of California–Los Angeles, and University of Michigan, before being appointed assistant professor at Washington University in St. Louis in 1969. Watson spent the remainder of her career at Washington University, retiring in 2004.

Watson was appointed Edward Mallinckrodt Distinguished University Professor of Anthropology at Washington University in 1993, a title she continues to hold as professor emerita. Throughout her long and distinguished career, Watson has held office in many professional organizations, received numerous awards for her achievements, and elected to several prestigious scholarly organizations, including the National Academy of Sciences (1988), American Academy of Arts and Sciences (1997), and American Philosophical Society (2000).

Major Accomplishments

Watson's dissertation research and early postdoctoral work in contemporary Iranian villages pioneered the use of ethnographical data as an analog to aid in the interpretation of past remains, a subspecialty now known as ethnoarchaeology. This work was published much later (Watson 1979) when archaeological ethnography became a subspecialty in its own right.

In the 1960s, Watson maintained her affiliation with the Oriental Institute of the University of Chicago, shifting her research focus to a Halafian site in the Diyarbakir region of southeastern Turkey (Watson and LeBlanc 1990), while Braidwood and his Turkish colleague Halet Çambel were conducting excavations a the nearby site of Çayönü. During this period, Watson formed important collaborations with Steven Leblanc, her first Ph.D. student, and Charles Redman, a student at the University of Chicago. LeBlanc and Redman's research interests in the Southwestern USA briefly drew her into field research in New Mexico (Cibola Archaeological Research Project); however, it was the publication of a short treatise on the philosophical underpinnings of archaeological inquiry for which they are best known.

In 1971, publication of *Explanation in Archeology: An Explicitly Scientific Approach* (Watson et al. 1971) was the first comprehensive statement of the "New Archaeology" or what came to be known as "processual archaeology." The book

helped foment a new approach to archaeology that emphasized the nature of scientific explanation, the scientific method, systems theory, and an ecological view of culture. This was followed by a second volume, published in 1984, that updated and extended their original arguments (Watson et al. 1984). By the late 1980s, advocates of post-processualism – the backlash against scientific archaeology – rejected the scientific method and processualism because of its overreliance on deterministic models and scientific objectivity, had become prominent. Watson spent the next two decades countering the critics of processual archaeology and a general antiscience bias among post-processualists (e.g., Watson 1991).

Watson remained ensconced in theoretical debates on the origins of agriculture and the philosophy of archaeological inference; however, in the late 1960s, her fieldwork began shifting to eastern North America. This happened somewhat by default because of her involvement with the newly organized Cave Research Foundation, of which her husband was a founding member. Unable to interest any North Americanists in the rich, well-preserved archaeological remains in caves of the Central Kentucky Karst, Watson began systematic documentation of prehistoric remains in Salts Cave, one of the large caves within the boundaries of Mammoth Cave National Park (Watson 1969). Salts and Mammoth caves had been extensively mined for mineral resources between 2,000 and 3,000 years ago. Among the perishable remains preserved in these caves were thousands of desiccated human paleofeces. In collaboration with the paleoethnobotanist Richard Yarnell, analysis of the paleofeces revealed a suite of indigenous plants in the early stages of domestication, known as the Eastern Agricultural Complex (Watson 1974). At the time, it was still thought that agricultural development in eastern North America was secondary to and dependent on developments that first occurred in Mesoamerica.

Armed with the exceptional data on early plant domestication from Salts Cave, Watson, in collaboration with her second Ph.D. student, William Marquardt, initiated the Shell Mound Archaeological Project to investigate prehistoric plant use just prior to the time period represented at Salts Cave. The middle Green River valley, just downstream from Mammoth Cave, was well known for large, freshwater shell middens dating 5,000–3,000 years ago. Marquardt and Watson employed the systematic use of water flotation recovery techniques to obtain carbonized plant remains from these sites. Their discovery, in 1976, of carbonized fragments of squash rind from 5,000-year-old midden deposits was the oldest record for a domesticated plant in eastern North America at the time. It has since been shown that not only does squash appear even earlier in the archaeobotanical record but that it was also independently domesticated in the Eastern USA (Marquardt and Watson 2005).

Watson's cave research and the Shell Mound Archaeological Project are still active, carried on by her students and a new generation of their students. The science wars have largely receded, replaced by a variety of interpretive archaeologies that emerged from the post-processual critique. However, as a model for archaeological inference, the scientific method, as advocated by Watson, is still the dominant model for selecting among competing knowledge claims and advancing archaeological knowledge.

Waynuna: Agriculture and Domestication

Daniel H. Sandweiss and Kurt M. Rademaker
University of Maine, Orono, ME, USA

Basic Site Overview

Waynuna (15° 16′ 01″ S, 72° 44′ 55″ W) is a multicomponent, open-air site located at 3,625 m above sea level (masl) on the eastern side of the Cotahuasi valley in southern Peru. The earliest component dates to the Late Preceramic (or Late Archaic) Period between 4,000 and 3,600 cal year BP based on the presence of diagnostic lithic artifacts and 10 radiocarbon dates (Perry et al. 2006). This component is significant for evidence of early highland plant domestication and interregional interaction (Perry et al. 2006, 2007). Later components are ceramic bearing and date to the last ~3,000 years (Jennings 2002).

Waynuna lies on a flat agricultural terrace in the shadow of Cerro Aycano (4,443 masl), about 400 m above and south of the modern village of Huillac or Huilla. Overlooking the Cotahuasi river (~2,700 masl), the site receives sunlight during most of the day. The ecotone between maize (*Zea mays*) and potato (*Solanum* spp.) cultivation zones today is at about 3,600 masl, where the site is located. Today, vegetation around Waynuna is dominated by thorny scrub growth (Figs. 1 and 2).

Justin Jennings (2002) discovered Waynuna (site CO-38 in his survey) in the late 1990s. He noted extensive terracing and four circular enclosures 8–10 m in diameter interpreted as animal corrals. In the center of the site were three 7-m diameter circular subterranean structures containing sub-chambers, niches, stone doorways, and beehive-shaped domed roofs, which perhaps served a special or religious function. Jennings found other surface architecture that he believed dated to the "Inchoate Period" (c. 2,850–1,200 cal year B.P.), and he recovered three diagnostic obsidian points that suggested an origin for the site in the Archaic Period, but he did not find evidence for a substantial domestic settlement on the site.

Subsequent test excavations by Sandweiss in 2004 found Middle Horizon (1,200–950 cal year BP) potsherds in the terrace fill. Underlying the terrace fill was a midden deposit lacking pottery and surrounding a circular stone house foundation approximately 2.1 m in diameter. It was these preceramic deposits that dated to 4,000–3,600 cal year B.P. The most abundant artifactual remains were fragments of obsidian, most of which were

Waynuna: Agriculture and Domestication, Fig. 2 Photograph of the west wall profile at Waynuna showing 2004 stratigraphic excavation. *Outlined arc* of stones in the photo is part of the Preceramic house, and the additional extent of the house is estimated

chemically sourced by Rademaker (2006, subsequent research) to the Cerro Condorsayana Alca-1 outcrops some 4.5 km distance at 4,700 masl; a few fragments came from Alca-5 outcrops, located 30 km away in the Pucuncho Basin at 4,400 masl.

Evidence of Early Agriculture

Linda Perry and Dolores Piperno (Perry et al. 2006, 2007) analyzed starch grains and phytoliths from the preceramic house floor, and they found evidence for domesticated maize, potato, chili pepper, and arrowroot. These data add to our understanding of early plant domestication in Peru. Early Holocene squash (*Cucurbita* spp.) macro- and microfossils have been recovered from northern Peru at Nanchoc sites on the western slopes of the Andes (Dillehay et al. 2007) and at the Siches site near the coast (Piperno 2011); Nanchoc also has early peanut (*Arachis* sp.) and cotton (*Gossypium barbadense*). The earliest known domesticated gourd in Peru comes from Early Holocene contexts at Quebrada Jaguay (Erickson et al. 2005), on the Pacific coast, some 150 km south of Waynuna. The microfossils from Waynuna constitute the earliest evidence for domesticated plants in the southern highlands of Peru.

Starch grains from maize, potato, arrowroot, and chili pepper were found adhering to grinding stones, suggesting that food was processed at the site. Patterns of damage on the maize starch grains indicate grinding, possibly to make *chicha* or corn beer, later a staple of the Andean diet (Perry et al. 2006). The chili pepper starch grains were identified as probably *Capsicum pubescens*, a species that includes *rocoto*. Today, *rocoto* is the signature pepper for Arequipa Department where Waynuna is located. Added to the suite of domesticates that are all still cultivated in the area today, the possible *chicha*-making, and the ecotonal site location, this specific identification supports the other indications that Waynuna stands at or near the beginning of a tradition in lifeways that continues to the present.

Maize and potato affirm the strategic ecotonal position of Wayuna. Arrowroot (*Maranta* sp.) only grows below 1,000 masl on the humid eastern side of the Andes, and the presence of this species in the arid, western Andes at Waynuna demonstrates long-distance (>300 km), interzonal interaction with the eastern lowlands. The obsidian sourcing data show regional interaction with higher-elevation zones at near and medium distances. Despite its location high on a mountain side above a remote Andean valley, these data show that Waynuna was not isolated but rather participated in an extensive trade or resource acquisition network, possibly on a camelid caravan route (see, for instance, Lynch 1983).

In summary, Waynuna was first occupied about 4,000 years ago by farmers who grew and processed potatoes, maize, and chili peppers. These first inhabitants maintained widespread relations with regions as near as the adjacent puna (high altitude grasslands) and as far as the eastern slopes of the Andes leading down to the Amazonian jungle. Later occupants of the site built terraces and other structures but apparently resided elsewhere. In modern times, although the agricultural terraces surrounding Waynuna are still farmed, the local people inhabit the village of Huillac, situated on the same ridge crest at slightly lower elevation north of the site.

WCCWiki

Claire Millington
King's College London, London, UK

Basic Information

#WCCWiki is an initiative run by the Women's Classical Committee UK (WCC UK) that seeks to achieve comprehensive representation on Wikipedia of women within all classical disciplines and has a strong focus on classical archaeologists. The project is run by volunteers from the WCC UK and the wider Wikipedia editorial community and is open to people of all genders who share the project's ethos.

The catalyst for the project was a growing concern within the classical community about the biases that exist within English language Wikipedia, including a systemic lack of representation of women as editors and as subjects. Wikipedia's purpose was set out by its founder, Jimmy Wales, to provide free access to the sum of all human knowledge (Wales 2016). However, demographic biases within the population of editors mean that systemic biases are written into the encyclopedia's content. Research into the gender of Wikipedia editors shows there to be a large gender gap, with women being underrepresented (Bayer 2015). A lack of recognition of the achievements of women is the result. Wikipedia consistently ranks within the top ten of the world's most visited websites, and its content is routinely reproduced on Google and embedded elsewhere. This means its biases are perpetuated far beyond the encyclopedia itself. #WCCWiki works to eliminate the gender skew and ensure the fair representation of women in the encyclopedia from the full range of classics disciplines, including classical archaeologists.

The project builds on the Wikipedia "editathons" held by the Trowelblazers, and by Dr. Debbie Challis, then at the Petrie Museum, that aimed to foreground women within archaeology, geology, and paleontology. It also takes inspiration from the impulse to find classical foremothers arising from the "Women as Classical Scholars" conference held in 2013 by the University of Notre Dame and King's College London. Following the foundation of the WCC UK in 2015, and with the support of trainers from Wikimedia UK, the #WCCWiki project was designed to replicate this success.

Major Impact

The core activities of #WCCWiki are to train women with knowledge of classics and archaeology to edit Wikipedia and to support people of all genders working to improve Wikipedia's coverage of women in classical disciplines. Wikipedia's systems of categorization mean that comparison of changes over time is not straightforward (Nevell 2018). However, figures provided by Wikimedia UK suggest that in January 2017 there were over 200 biographies of classicists on Wikipedia, but only around 10% of these were of women. Similar research in December 2018 found there were 2088 biographies of classicists on the English language Wikipedia, of which 268 were

of women (12.88%), and 193 biographies of classical archaeologists, of which 37 were of women (19.17%) (Nevell 2018).

WCCWiki is managed entirely by volunteers. The project is run from its project pages on Wikipedia, which includes a list of entries that need creating or improving, as well as bibliographical resources, details of forthcoming events, and a calendrical list showing pages that project editors have created or improved. By categorizing the pages in need of creation or improvement according to work required, participants can more quickly find editorial tasks, such as checking pages for updates, that require little time or energy.

Drop-in editing sessions are held online on a monthly basis, using an open chat channel to discuss the project's work and to provide support to editors. Periodic in-person meetups and training events are held at varying locations, including at the University of Kent, the University of Manchester, the University of Birmingham, the Institute of Classical Studies in London, the Institute of Archaeology (UCL), and the University of Oxford. However, the project functions mainly in an online environment, which minimizes the time and cost to participants who are often early career researchers and may not be in the UK.

Ongoing discussions of the project also take place on the project's "talk page," via the hashtag #WCCWiki on Twitter and on the Women's Classical Committee Facebook page. Other hashtags such as #NoPageRage, #Foremothers, and #VisibleWikiWomen connect the project on Twitter with wider discussions about the lack of female representation on #Wikipedia. Particular strands of work are to improve visibility of women by obtaining images of article subjects and to improve the coverage of women from ethnic minorities and women of color, such as Helen Maria Chesnutt. Article translation between mainly European languages is also undertaken by project editors. The project engages with similar women-focused groups, including Women in Red, who highlight the missing women in Wikipedia by inserting redlinks for absent pages, and the Classical Association of Canada's Graduate Student Caucus.

Wegener, Corine

Corine Wegener
U.S. Committee of the Blue Shield, Minneapolis, MN, USA

Basic Biographical Information

Corine Wegener received her Bachelor of General Studies degree in political science from the University of Nebraska-Omaha and Master of Arts degrees in both political science and art history from the University of Kansas. She is the Cultural Heritage Preservation Officer in the Office of the Under Secretary for History, Art, and Culture at the Smithsonian Institution in Washington, DC.

Major Accomplishments

As a major in the U.S. Army Reserve, Corine Wegener served as the Arts, Monuments, and Archives Officer for the 352nd Civil Affairs Command in Baghdad, Iraq. Her duties included assisting the staff of the Iraq National Museum with the recovery and preservation of their collections after the looting during the US invasion of 2003. As a result of that experience, she founded the U.S. Committee of the Blue Shield in 2006, a nonprofit organization dedicated to US ratification and implementation of the 1954 Hague Convention for the Protection of Cultural Property in the Event of Armed Conflict. She continues to serve as President. In 2007, Wegener developed a Blue Shield training program for US military personnel, designed to familiarize them with the 1954 Hague Convention. Over the past 3 years, she has organized nine military training sessions for approximately 570 US military personnel, working closely with partner organizations, the Archaeological Institute of America (AIA), the American Institute for the Conservation of Historic and Artistic Works (AIC), and the Smithsonian Institution, all of which provide volunteers, travel funds, and/or facilities. Wegener helped establish the Smithsonian Haiti Cultural Recovery Project after the 2010 Haiti earthquake. As the International Project Coordinator, she helped launch and equip the Cultural Recovery Center in Port-au-Prince and led the first teams of conservation volunteers to arrive in Haiti. Volunteer conservators and Haitian colleagues and trainees recovered, restored, and treated over 30,000 works of art, works on paper, books, and historical documents over the course of 18 months. She has written and lectured widely about her experiences with cultural property

protection and the Blue Shield. She serves on the board of the U.S. Committee of the International Council of Museums (ICOM), the ICOM Disaster Relief Task Force; is secretary of the Association of National Committees of the Blue Shield; and vice president of the U.S. Military Civil Affairs Association.

Weidenreich, Franz

Julie L. Cormack
Department of Sociology and Anthropology, Mount Royal University, Calgary, AB, Canada

Basic Biographical Information

Franz Weidenreich was born on 7 June 1873 in Edenkoben, Germany, and died in his New York City home on 11 July 1948. Gregory (1949: 85) described Weidenreich as "the flower of German science and true culture" with an "indefatigable energy and constructive intellect." He graduated from the Humanist Gymnasium in Landau, later spending some 6 years studying medicine and general sciences from a number of German universities in Berlin, Kiel, and Munich. He eventually received an M.D. from the University of Strasbourg in 1899. His research interest was the anatomical structure of the mammalian cerebellar central nucleus, and after his graduation in 1901, he worked under the direction of Gustav Schwalbe in the Department of Anatomy at Strasbourg. Upon expanding his research into blood and lymphatic systems, which took him briefly to the University of Frankfurt, he returned to Schwalbe's lab in 1902 where he was appointed Professor of Anatomy two years later. By 1914, Weidenreich had published 55 research papers, primarily on the topic of hematology. But in his early writings were found a scientific curiosity of human evolution, where he published a couple of papers on the origins of the human chin and its relationship to speech, and a comparison of human and ape pelvic and lower limb anatomy to locomotion. In 1926, he published his first "official" paper on Anthropology, an anatomical description of the Weimar-Ehringsdorf fossil human skull.

Between 1914 and 1921, he wrote few scientific discourses and instead focussed his energies as a member of the Municipal Council of Strasbourg, and President of the Democratic Party of the disputed territory of Alsace-Lorraine. With the French takeover in 1918, Weidenreich lost his Strasbourg academic position, but by 1921, he was established in the Department of Anatomy at the University of Heidelberg. Seven years later he took the position of Professor of Anthropology at the University of Frankfurt, where he stayed until 1934 when a visiting professorship in Anatomy at the University of Chicago became available. In the fall of that year, Weidenreich was considered for a teaching position at the Peking Union Medical College with the death of Davidson Black, in Beijing, China. This consideration was confidently recommended by one

of Black's closest friends, (Sir) Grafton Elliot Smith.

Weidenreich's appointment as Visiting Professor of Anatomy at the PUMC and Honorary Director of the Cenozoic Research Laboratory, a collaborative facility (between the PUMC and the Geological Survey of China) that focussed on the analysis of fossil and cultural materials from the Zhoukoudian (Peking Man) site began on January 1, 1935. With intense fighting between various Chinese factions and the Japanese, Weidenreich eventually left for the United States in 1941, where he took his last research position, this time at the American Museum of Natural History in New York City.

Major Accomplishments

During Weidenreich's tenure at the Peking Union Medical College, he took on similar responsibilities to Davidson Black: describing and publishing on the *Sinanthropus* fossil material from Zhoukoudian, collaborating with Chinese and other foreign scientists, and working with the Rockefeller Foundation to continue funding the excavations and the Cenozoic Research Laboratory work.

However, he added new dimensions to the Zhoukoudian scientific program. First, he recognized an anatomical similarity between the Chinese *Homo erectus* (*Sinanthropus*) and Indonesian *Homo erectus* (or *Pithecanthropus* originally found by Dubois in the 1890s), developed in collaboration with G.H.R. von Koenigswald whom he visited in Java in 1937. Together, they "sank" *Sinanthropus* into the older *Pithecanthropus* label, eventually leading to the combining of the Chinese and Indonesian fossils into a single genus (originally speculated by Black) known as *Homo erectus*. The following year, these two scientists announced a new fossil skull from Java (*Pithecanthropus robustus*).

Second, he took a unique taphonomic perspective to the stratigraphic levels at Zhoukoudian, suggesting that some of the scattered fossil remains were the result of activities by carnivores. In one publication, he even suggested that some human skulls (only represented by the skullcap) were victims of murder, claiming that lengthy cracks and deep punctures in the bony structure were the result of violent blows to the head!

Third, he examined the more modern human skeletal remains from Zhoukoudian's Upper Cave as possibly representing different racial origins, including Mongoloid, Melanesian, and possibly Inuit, creating a hypothesis of interracial heterogeneity for the upper reaches of the Peking Man site.

Fourth, and most significantly, with continued military incursions around Zhoukoudian and infiltration into Beijing, Weidenreich and his Chinese colleagues (in particular Pei Wenzhong) arranged for the manufacture of a series of replica casts of the original *Sinanthropus* fossils, which would eventually be housed at the American Museum of Natural History. In addition, the originals of the most significant of the *Sinanthropus* fossils would be transported out of Beijing, and out of China. Sadly, the original fossils became lost, but the replicas (and further discoveries) of *Sinanthropus* are still available for scientific study.

Wells, E. Christian

E. Christian Wells
Department of Anthropology, University of South Florida, Tampa, FL, USA

Basic Biographical Information

Christian Wells received his B.A. from Oberlin College and his M.A. and Ph.D. in Anthropology from Arizona State University. He was trained in economic and environmental anthropology and archaeology. He is currently Professor of Anthropology at the University of South Florida, where he holds affiliate appointments with the College of Global Sustainability, the Water Institute, and the Institute for the Study of Latin America and the Caribbean. He is a member of the editorial boards for *American Anthropologist* (American Anthropological Association), *Archaeological and Anthropological Sciences* (Springer–Earth Sciences), and the *Journal of Agriculture, Food Systems, and Community Development* (New Leaf Associates).

Major Accomplishments

Dr. Wells is the Professor of Anthropology and Director of the Center for Brownfields Research at the University of South Florida, where he has served previously as Founding Director of the Office of Sustainability and Deputy Director of the Patel School of Global Sustainability. His research focuses on understanding how cultural and natural resources are increasingly impacted by global tourism. Over the past 20 years, he has undertaken social and environmental science research throughout the United States, Mexico, Central America, and the Caribbean.

He is especially known for developing methods to extract and characterize inorganic anthropogenic residues from soils and sediments associated with archaeological sites (Wells and Terry 2007). He has lectured and published widely on human impacts to the physical and chemical properties of soils over time and developed the theoretical concept of "cultural soilscapes" to characterize these impacts (Wells 2006).

His current research examines the effects of mass tourism on sustainable development, critical infrastructures, and human and environmental health (especially soil and water systems). His latest book (Lyon and Wells 2012), *Global Tourism: Cultural Heritage and Economic Encounters*, brings together ethnographers and archaeologists to explore the various ways in which hosts, guests, cultural patrimony, and natural resources intersect in the global economy of tourism.

West Africa: Islamic Archaeology

Sam Nixon
Sainsbury Research Unit for the Arts of Africa, Oceania and the Americas, University of East Anglia, Norwich, UK

Introduction

Unquestionably, West Africa is presently on the periphery of the discipline of Islamic archaeology, even more so than other "peripheral" areas such as the East African coast. This position within the discipline relates principally to Islamic archaeology's origins in the study of Middle Eastern material culture and its emphasis on art and architectural models that are simply not present in West Africa. West Africa, though, has been home to Islam for over 1,000 years and like elsewhere in the Islamic world has seen the development of wide-ranging cultural networks, powerful Muslim dynasties, and varied architectural and material-culture traditions. It represents perhaps one of the greatest untapped zones of Islamic archaeology, with major settlements never touched and material traditions of whole dynasties poorly understood. For an increasingly global Islamic archaeology, West Africa's "difference" actually becomes a strength (Whitcomb 2004) as we seek to diversify ideas of the cultures and material remains of Islam. Additionally, increasing prominence of West Africa within the contemporary landscape of Islam will almost certainly lead to growing interest in its past cultures and remains.

Definition

The most commonly accepted definition of Islamic archaeology is that it represents the study of all material remains in areas where the ruling elite was Muslim (Milwright 2010: 6–8). This certainly poses major problems in West Africa where Islam seemingly moved into territories not with rulers but with small enclaves of traders, and in some areas centuries passed before ruling elites adopted Islam. Based upon experiences in West Africa, Insoll (1999) has sought an alternative definition, maintaining that there are a range of Muslim behaviors that consistently create distinctive material-culture signatures and that this knowledge can be the basis for studying past Muslim societies regardless of the presence or not of a ruling Muslim elite. Within the West African context, Islamic archaeology is perhaps most usefully approached in a very open way as the research of remains relating to all past Muslim communities and their cultural networks, as well as of non-Muslim groups controlled by Muslim elites.

The material evidence defined as Islamic archaeology in West Africa has tended to be either material remains which are *excavated* from the earth or standing *ruins* of past settlements. Standing buildings which still function and ethnographically documented material-culture traditions have generally been the domain of art historians or anthropologists (e.g., Prussin 1986). Arabic inscriptions on rocks and tombstones have been the preserve of epigraphy (Moraes Farias 2003).

There is in fact really no such recognized discipline as "Islamic archaeology" in West Africa, and very few people actively seek Islamic remains or position themselves as an "Islamic archaeologist." Therefore, even though remains related to Islamic societies are recovered, they are often not properly investigated for the insights they can provide into the Islamic past. Going further, Islamic elements of past West African societies have often been actively sidelined, due to negative associations with the colonial-era belief in the importance of "Arab stimulus" for past cultural developments in West Africa. Related to this, the archaeology of Islamic societies is often approached as just one element of a wider concern with "precolonial" societies (i.e., those preceding the presence of European colonialism). The archaeology of the Islamic period is also often described using the terms "medieval" or

"postmedieval," terms which have been heavily criticized as having little relevance to West Africa's past.

There does seem to be a relatively broad consensus concerning the definition of periods in the history of West African Islam, despite the process of Islamization having been a long and complex one from around the eighth or ninth century until the nineteenth when Muslim presence first roughly approximated today's landscape (see "Historical Background" section). This picture broadly corresponds to the "early Islamic," "later Islamic," and "modern" periods discussed in the Central Islamic lands. While it would be inappropriate to apply this periodization or these labels too strictly, this does provide some means of relating Islamic history in West Africa to movements elsewhere.

Within the context of this entry, "West Africa" should not be too simplistically understood as all the territory occupied by modern West African states, as these territories are relatively arbitrary creations of the colonial and postcolonial era and provide a weak basis for discussing the Islamic past. For instance, the West African state of Mauritania extends c. 1,000 km further north of the southern extremity of the North African state of Algeria. This said, contemporary West Africa broadly approximates to a clearly defined zone within the *Bilād al-Sūdān*, or "land of the blacks," defined by early Arabic authors in Central Islamic lands. The area south of the Sahara from the Atlantic to Lake Chad was understood as an extremely rich zone of gold and slaves (as well as ivory and the mild stimulant the kola nut), becoming known particularly as "the land of gold" throughout the Islamic world. This area also had a rich tradition of states and empires, from Islam's arrival up to the colonial era. While West Africa represents a useful geographical category for thinking about Islamic archaeology, the diversity of this region must be recognized. This includes the gradual shift from the nomadic semi-desert in the north to the dense agriculturalist-occupied forest zone in the south, and a broadly related shift from a Berber (principally Tuareg) population in the north to a black population in the south.

Today, West Africa is a mosaic of Islamic, Christian, and animist groups. Arabic has historically not been the dominant language throughout Muslim West Africa, though it certainly has scholarly status, and in Mauritania is the official language.

Historical Background

External Arabic historical sources first describe Islam in West Africa around the eighth century CE, associated with traders seeking the wealth of gold, slaves, and ivory to be found there (Levtzion and Hopkins 2000). These traders used camel caravans to cross the Sahara (see Fig. 1), in an era before sea transport along the Atlantic coast (only commencing with Europeans in the fifteenth century) and prior to east–west routes connecting with the Horn of Africa (likely commencing *c.* fourteenth century). For several centuries Islam was largely restricted to traders, albeit converted indigenous traders as well as immigrants. Islamic settlement was also largely restricted to the southern Sahara and the zone immediately below the Sahara known as the "Sahel" (in Arabic, "shore"), at places such as Audaghust, Tadmekka and Kawar (see Fig. 1). This arid, sparsely populated area was the first habitable zone after the Saharan crossing and therefore was an ideal point to serve as a trading base supplying Saharan caravans with products collected from throughout West Africa. From the eleventh century, Islam began to spread further south, a process which in the western regions was significantly aided by the militant Almoravids, who waged holy war, including converting the ruler of the most powerful early kingdom, Ghana (not to be confused with the modern state of Ghana). The other most important early kingdoms, Gao and Kanem, also now appeared to experience increased Islamization. The start of the "Golden Age" of West African Islam however came in the thirteenth/fourteenth centuries and is particularly associated with the growth and expansion of power of the Empire of Mali (not to be confused with the modern Republic of Mali) and its most famous ruler, Mansa Musa, known throughout the early Muslim

West Africa: Islamic Archaeology, Fig. 1 Map of West Africa showing key locations referred to in the text and trans-Saharan trade routes

world for his wealth in gold. The first significant records of West African rulers' *hajj* journeys also occur now (both of Mali and Kanem), as does the development of Timbuktu (Fig. 2), West Africa's most famous city, which became a celebrated center of Islam noted for its libraries and mosques.

During the fifteenth and sixteenth centuries, Songhay, the last of the great premodern empires (developing from the ancient state center of Gao to inherit Mali's power), helped push Islam beyond its traditional heartlands deeper into the savanna and forest regions. Songhay's expansion even encroached on the kingdom of Bornu, now the successor state of Kanem in the east. The Moroccan invasion of West Africa in the late sixteenth century destabilized Songhay, and it was not until the nineteenth-century jihadist movements that Islam truly became a religion of the common people and the village. Despite a European coastal trading presence from the fifteenth century, it was not until the colonial era that Christianity developed significantly.

West African archaeology began in the mid-nineteenth century, a process intertwined with the European exploration of the African "interior" (Timbuktu itself was only finally visited and returned from by a European in 1822). Explorers pursued living cities but also the remains of past civilizations which the growing study of external Arabic records and local Arabic *tarikh*s was helping to reveal (Es-Sa'di 1900; Cooley 1841). Mainly, however, there was a focus on understanding the "traditional" or indigenous African past and this was often contrasted with Islam, despite Islam's very long history here. Already though, it could be seen that Islamic ruins in West Africa were of a very different character to those found in much of the Islamic world, including an apparent lack of monumental tiled and Arabic-inscribed architecture. While the vast majority of scholars were not fundamentally interested in Islamic remains, certain important studies were done, including the groundbreaking work of De Gironcourt (1920) who recorded the relatively extensive presence of funerary and non-funerary Arabic inscriptions (found mainly in the modern Republic of Mali, dating from the eleventh to fifteenth centuries CE). One crucial idea put in place at this time was the belief that cultural advances among West African populations had been due in large part to the "stimulus" of Arab contact.

Huge progress came in the 1950s and 1960s, largely through the work of Mauny who systematically charted "medieval" sites throughout West Africa (Mauny 1961). Focused studies also took place at such important sites as Gao, Koumbi Saleh, and Tegdaoust (associated with Audaghust). The latter in particular saw commencement of systematic investigations lasting decades (Devisse 1983). These investigations uncovered compelling evidence for sophisticated early Islamic architecture and trade imports. Certain broader reflections also started to be made concerning West African Islamic material culture, including observation and discussion of the distinct absence of locally produced Islamic coinage. Within this same era archaeology continued to uncover new evidence for the richness of West African cultures not documented by Arab sources, such as Ife and Benin, and this perhaps attracted more research interest than sites seemingly already well documented by Arabic sources.

The 1970s and 1980s began to turn up evidence that enabled scholars to begin to overturn the "Arab stimulus" hypothesis for complex society development in West Africa. A key discovery was made close to the important later Islamic town of Djenne, namely, a pre-Islamic urban site with evidence of significant long-distance trade contacts (McIntosh 1995). Further east, in the zone of Kanem-Bornu, similar evidence also emerged at Daima and Kursakata (see Gronenborn 2001).

While the preference for investigating "indigenous" pasts in contrast to Islamic pasts has been dominant, certain important studies of Islamic remains have occurred. Since the 1980s the epigrapher Paulo de Moraes Farias has illuminated the corpus of Arabic inscriptions, demonstrating their ability to provide detailed and fascinating accounts of early Islamic cultural processes (2003). Timothy Insoll's excavations, most notably at Gao (see 2003), but also at Timbuktu, provided further evidence of archaeology's potential to investigate trade and architectural history. Among other works, Cressier addressed the study of Sufi archaeology in the Sahel (Bernus et al. 1999). More recently, work at Tadmekka by the author (Nixon 2009) reconsidered how archaeology can provide insights into trans-Saharan trade. As archaeology of the last two millennia in West Africa continues apace, other projects not specifically concerned with Islam continue to turn up

Islamic remains, including work within the Kanem-Bornu region at sites such as Garumele or Birni Gazargamo.

Key Issues/Current Debates

Most investigation of Islamic archaeology in West Africa has taken place within the context of wider investigations of West African culture of the past two millennia, with little reference to developing debates elsewhere within Islamic archaeology. Often, investigations have related to agendas created by historians grounded in the study of the Arabic records of the region. Despite this, a clear and distinct body of debates has developed which recovery of Islamic remains feeds into.

The Chronology, Geography, and Culture of Early Islamic Contact

Arabic sources clearly indicate how Islam's arrival in West Africa occurred within the context of trading ventures across the Sahara for gold, slaves, and ivory. A core ongoing debate has been attempting to understand the early chronology and geography of this trade. Although it is clear from Arabic sources that by the tenth century CE, significant trade contacts were in place across all Saharan routes, the question of whether historically undocumented trade occurred before this, and if so where, has long divided opinion. Archaeological excavations associated with the main trading town on the westernmost route, Audaghust, have not recovered clear evidence of pre-tenth-century contacts (Devisse 1983), but recent excavations at Tadmekka further east provided compelling evidence of trade at least back to the ninth century (Fig. 3; Nixon 2009; Nixon et al. 2011). The major oasis center of the Central Saharan route, Kawar (Lange and Berthoud 1977), has never been excavated, and therefore suggestions of pre-tenth-century trade here have been impossible to verify. It is in fact increasingly believed that early Islamic trade was built on strong pre-Islamic commerce in gold and slaves across the Sahara. The most compelling argument for this comes from the site of Kissi (Burkina Faso) where evidence for trans - Saharan imports can be traced from the first to the twelfth century CE (Magnavita et al. 2009).

Clarification of when trade developed is paramount, as it is central to debates over the extent to which external contact contributed to West African development. Likewise, understanding the geography of early Islamic connections is obviously important for a basic understanding of Islamic networks, but also relates to understanding the development of the states with which early Muslims traded. While Ghana in the far west has long been seen as the preeminent early West African power, evidence of early trade further east asks us to consider whether other early West

African states such as Gao or Kanem were equally important.

The identity of the first Islamic traders has been strongly debated by historians. The most prominent traders were long seen to be North African Zenata Berbers. Other historians have pointed to documentary evidence also indicating the important trading role of the Ibadi, a splinter sect of Islam who dispersed into the Sahara soon after Islam's arrival in North Africa. There is some documentary basis for suggesting that the Zenata were mainly concentrated on the westernmost route, with the Ibadi on routes further east. Excavated material culture from Tegdaoust and Tadmekka shows distinct differences between the western and eastern routes, but there is little comparative "Zenata" or "Ibadi" material from North Africa to test this against. Surface remains of mosques and cemeteries at Tadmekka and Kawar (see Insoll 2003: 206–262) are however suggestive of the early Ibadi. Clarification of this issue is important in order to understand the ethnic and religious nature of the first populations who communicated Islam to West Africa.

The Landscape of Settlement

There has been considerable interest in understanding how Islamic settlements developed throughout the landscape. Unsurprisingly, focus has been on the first settlements created at the southern edge of the Sahara. The excavations at Tegdaoust and Tadmekka suggest a lack of pre-Islamic urban phases but the existence of permanent architecture from *c*. ninth century CE. These towns appeared to continue as central places right up to the thirteenth/fourteenth century, despite the development of competing regional centers. While their vicinities are not systematically surveyed, it appears they were largely isolated in a wider nomadic environment, which accords with historical descriptions.

Away from the desert's edge, the model for initial Islamic settlement has long been one of small enclaves of traders developing close-knit communities in proximity to, but clearly separate from, capitals of local states. Archaeology has provided solid evidence of this at Gao, where a trading settlement appears to have developed 2 km from the royal settlement (Insoll 2003), and epigraphy (e.g., Fig. 4) has provided great insight into this process. While a similar "dual town" scenario is described by Arab records for Ghana, its capital has never been clearly located, although Koumbi Saleh has contentiously variously been seen as either Ghana's capital or its traders' town (see Insoll 2003). Further east, the earliest capital of Kanem has also not been found. Examples of similar "dual towns" have been proposed for other locations, including for Kukiya, downriver of Gao. While the Sahel/savanna zone

West Africa: Islamic Archaeology, Fig. 4 Arabic inscriptions from the Republic of Mali: left, imported early twelfth-century gravestone from Gao; right, drawing of locally made gravestone from Kukiya (© The British Academy 2003)

would become the heartland of West African Islam through the twelfth to fourteenth centuries CE, we have little idea of the growth of fully fledged Islamic towns. While some evidence exists from Gao, not only have we not found the capitals of Ghana and early Kanem, whose rulers supposedly converted to Islam, the capital of Mali remains undiscovered. Supreme Islamic towns such as Timbuktu and Djenne have also yet to be properly investigated. Excavations have taken place at Dia (Bedaux et al. 2005), seen as a regionally significant early Islamic center, but so far there is no clear idea of how this relates to the larger picture of Islamic settlement.

At some point during the fourteenth to sixteenth centuries, there was a further spread of Islamic traders and settlements southward to the forest fringes. The Arabic historical sources however provide limited insight into this, and therefore archaeology takes on even greater importance. One significant settlement which has been excavated and shows Muslim presence at the forest fringe from this era is Begho in modern Ghana (Stahl 1994). The whole question of settlement in this zone is, though, poorly understood. Accounts of later phases of settlement, including the nineteenth-century *jihad*s, are almost entirely based on historical records and oral tradition.

Islamic Architecture

Traditional Muslim building in West Africa is most associated with mud architecture and particularly with the Western Sudanese style, most synonymous with the legacy of Mali and Songhay (i.e., Fig. 2). This architectural style is most commonly linked to mosques, with characteristic features including flat roofs, vertical buttresses, and pyramidal minarets, with protruding wooden beams/branches acting as both structural support and decoration (Prussin 1986). While structures are mainly composed of mud-brick, wet mud is periodically added during renovation like plaster. Architecture in a broadly similar style is found right across the Sahel and savanna belt of West Africa. The Western Sudanese style has long been linked with the influence of the fourteenth-century immigrant Andalusian architect al-Saheli, but modern commentators, seeing this story as mythical, point out strong relationships with early Ibadi architecture or claim it as an entirely indigenous building style (Aradeon 1989). The oldest standing structures in this style supposedly date back to the fourteenth century but have clearly undergone extensive renovation. There are no clear excavated examples of the Western Sudanese style, or pre-fourteenth-century documentary evidence, to help us understand its origins.

Mud-brick architecture in West Africa is a highly developed tradition, linked to specialist "masons," but it is still unclear whether this "technology" is associated with Islamic influence. Archaeology has shown broad zones of difference in mud-brick form, most importantly a difference between a rectangular mud-brick tradition in the Mali/Songhay zone and the cone-shaped *tubali* bricks of northern Nigeria. Fired brick has also been found in significant quantities, especially in the Kanem-Bornu zone (e.g., Garu Kime). Fired brick is also present at Gao, in the form of a fired-brick *mihrab* and portions of what appears to be a *caravanserai*. There is no evidence of tiling, though such a tiled structure might still be found, especially given Arabic records' apparent indication of an elaborate audience hall at the still undiscovered Malian capital of Niani. Plaster and paint are both evidenced in early excavated contexts, including abstract painted designs at Koumbi Saleh and thick ochre plaster at Tadmekka, tying in with ethnographic examples (Prussin 1986).

Stone architecture, while little present today (e.g., Chinguetti, Mauritania), was clearly more common in the past. The early sites of Tegdaoust and Tadmekka (Fig. 3) are defined by stone ruins. The trading town of Ghana was also supposed to have been of stone in the eleventh century. Other stone ruins include Koumbi Saleh (Mauretania) and the Almoravid settlement of Azugi (Mauritania). That the majority of these stone towns are in the northern Sahel certainly relates to the distribution of available stone but also to the greater presence of Berber populations here who have stronger traditions of stone architecture.

A core formal division is made in West African archaeology between Muslim and non-Muslim

architecture based, respectively, upon the presence of rectilinear or circular forms. This does not always apply though, as observed by Insoll (2003: 325). Again, it would be important to recover building forms from significant early towns such as Timbuktu to progress this debate. Studies of individual building form, functional types, and decorative design in Islamic architecture in West Africa are a lively tradition in art-historical studies (Prussin 1986), but this has so far not translated into archaeology. Most strikingly, there has been a relative inattention to mosque design. There is, however, already a relatively useful collection of archaeologically occurring evidence, including the fired-brick mosque in Gao, the stone mosque of Koumbi Saleh (Fig. 3), surface evidence of mosques at Birni Gazargamo and at Tadmekka (including a *musalla*), and excavated examples of Sufi mosques from Niger (Bernus et al. 1999).

Beyond building materials and basic formal distinctions, there has been an interest in certain other additional elements in building design. Wooden doors are known from historic-era towns of the Sahel, and the recovery of keys and locks from early northern Sahelian ruins indicates the long history of this (Berthier 1997; Nixon 2009). While the presence of window glass is open to debate, we do have evidence of ceramic window grills (Fig. 5) and wooden windows from museum collections.

Another strain of research briefly to note concerns town walls. We see these particularly in both the Malian zone, in northern Nigeria, and in Niger. Not only are walled towns well documented from recent historic periods, they have also been evidenced at older abandoned sites, including one of the ancestral Hausa sites, Kufan Kanawa (Haour 2003).

Trade

Since the start of excavations in West Africa, there has been research into Islamic trade goods from across the Sahara. The most common goods evidenced are glass beads, vessel glass (often merely fragments, but also some reconstructable vessels: e.g., Fig. 6), and glazed ceramics. Core commodities that also travelled and are found in relative abundance are brass ingots, most strikingly at the abandoned Saharan caravan site of Ma'aden Ijafen in Mauritania (2085 brass bars). Other obvious but less common durable markers of trade include ornately inscribed brass bowls (e.g., Gronenborn et al. 2012) and tombstones

from Spain (Fig. 4). While many sites do not feature these goods, this likely indicates not lack of trade but rather movement of other goods more difficult to detect archaeologically. A core item which has largely eluded us are textiles (see however Nixon 2009), suggested by historical sources as perhaps the most important early trade good. We are now also starting to think more critically about the trade goods which are present. Restriction of vessel glass and glazed ceramics largely to the Sahelian towns suggests perhaps that these were commodities mainly for consumption by traders themselves. The wider distribution of glass beads is more complex, especially as their greatest concentrated occurrence has been in non-Islamic graves far to the south (Igbo-Ukwu, Nigeria) in very early contexts (radiocarbon dated eighth to twelfth century CE; see Insoll 2003: 347–8).

The core commodities which the central Islamic world desired from West Africa are all items which are of poor archaeological visibility: gold, slaves, ivory, and kola nuts. Despite this, the crucial gold trade at least has seen some good archaeological insights. A mainstay of the study of the gold trade has been analysis of North African dinars, the majority being made of West African gold (dinars have also been recovered in West Africa at Tegdaoust and Gao). Increasing evidence of locally worked gold has been found, at Tegdaoust (ingots), Djenne (earring), Gao (bead), Durbi Takusheyi (jewelry), and Tadmekka (coin-blank moulds). The Tadmekka evidence demonstrated that West African gold attained an extremely high purity (98–99%), further explaining the Muslim world's fascination with it. While early Arabic sources refer mainly to the gold mines of Bambuk and Buré (Fig. 1), wider distribution of gold finds requires us to consider other important sources, including the Sirba gold fields (Niger and Burkina Faso). Archaeological finds of ivory exist (e.g., the hippo ivory cache at Gao), and slave-trade archaeology is developing, but the kola trade has so far seen little input from archaeologists.

The Tadmekka moulds have provided the only concrete evidence to date of locally produced coinage in West Africa, being proof of the "bald" (i.e., unstamped or blank) "coinage" described by early Arabic sources here (Nixon et al. 2011). While there may have been a range of such unstamped "coinages," the only documentary records of inscribed coinages are a fourteenth-century reference to Kanem silver coinage and a fifteenth-century description of West African silver coinage in Egypt (see Nixon et al. 2011). We do however have clear evidence for the adoption of the Islamic weight system, in the form of not only Fatimid glass weights (Tegdaoust) but also rudimentary, locally produced ceramic disc weights, and locally produced metal weights. Archaeology also provides extensive evidence of cowrie shells, a major import from the Indian Ocean to serve as money.

Technology and Local Material Culture

Since early in West African archaeology, much discussion has concerned whether certain technologies present in West Africa should or should not be attributed to Islam's arrival. Metalworking technology is the most contentious topic. The basic starting point for discussion is certainly that indigenous metalworking was highly proficient before Islam's arrival, particularly iron and copper. One specific technology that has led to an extensive but unresolved debate is the highly complex "lost wax" casting process, present in West Africa seemingly as early as the tenth century CE. In addition to evidence for imported brass, there is also evidence now for local brass working (Stahl 1994). Recent metallurgy studies at Tadmekka also indicate the presence of highly technical crucible steel working. Another important area of debate is textile production. Arabic sources strongly indicate the prevalence of skins for clothing prior to Islam's arrival, but it is unclear whether this was allied with an indigenous textile tradition. Certainly, restrictions on exposing the body would have led to an increased need for clothing, and all archaeobotanical evidence of cotton and spindle-whorl finds indeed postdate Islam's arrival.

Among glazed ceramics recovered, none appear to be locally produced. Likewise, analysis of vessel glass suggests that this was all imported. Glass-bead production is not totally absent from

West Africa: Islamic Archaeology, Fig. 7 Muslim male potters in Niger placing pots in preparation for a firing. (Image courtesy Olivier Gosselain)

West Africa, there being evidence for both primary glass and glass-bead production at Ife in Nigeria (*c*. twelfth century CE) and also evidence for powder glass beads from Mauritania in historic times. Suggestions of a more widespread and early tradition of glass-bead making are rather questionable, being based mainly on the presence of malformed beads or bead wasters, actually commonly included in large bead exports. We have already spoken about the apparent absence of inscribed coinage. The lack then of West African examples of these material-culture types has certainly gone a considerable way to placing West Africa outside familiar territory for many in Islamic archaeology.

Art historians and anthropologists have been highly engaged in demonstrating the wide range of material-culture forms of the historic and contemporary Muslim world in West Africa (Bravmann 1983; Prussin 1986). Archaeologists have been less successful, leading perhaps to a perception of early material-culture poverty of Islam in West Africa. Certainly, archaeology has not been well aided by the perishability of the materials which ethnographic collections suggest much early Islamic material culture in West Africa would have been created in, such as leather, wood, and textiles. Locally produced Islamic material culture is certainly not absent, however. Ubiquitous pottery naturally comes to mind, and while traditions of pottery associated with Islamic groups in West Africa are perhaps better defined in the anthropological literature (Fig. 7), the implications of this for archaeologists appear promising. Survey also shows various other distinctive types of durable, archaeologically recoverable material culture, including ceramic fabricated items, such as spindle whorls, jewelry, and functional metal objects of everyday use (e.g., Fig. 8).

West Africa: Islamic Archaeology, Fig. 8 Padlock and key produced by Hausa metalworkers (Nigeria) and traded to Ashanti (Ghana) – collected in Kumasi (Ghana) in 1818. (© The Trustees of the British Museum)

International Perspectives

West African Islamic archaeology has involved a wide range of non-West African national research

teams but principally French, English, German, Dutch, and American, as well as a recent Japanese collaboration in Mali (Gao). West African national researchers are largely associated with government heritage and research agencies (see particularly Mamadou Cisse's work at Gao).

To date, West African Islamic archaeology has mainly been researched in Mali, Mauritania, Nigeria, and Niger. Contemporary politics in these countries linked to recent Islamic fundamentalist movements have obviously problematized this focus. The broad shift of international projects to other countries will likely see more results relevant to Islamic archaeology from countries such as Senegal, Ghana, and Benin. Changing patterns of relations between Islam and the West presents a more nuanced situation for West African national agencies. Certainly though radical Islam sees all archaeological practice as problematic. However, more moderate development of a stronger Islamic consciousness might lead to more investment in the study of Islamic remains than the emphasis so far on prehistoric or "indigenous" archaeology.

While practical and political problems currently dominate the international outlook for Islamic archaeology in West Africa, we should highlight the need also for new impetus to link West African research more into the international scene. Certainly, there should be renewed efforts at establishing broad theoretical connections, but also this might be aided by comparative approaches with other more peripheral areas of the Islamic world. Most obviously, there is the East African coast, but also perhaps Silk Road archaeology, which is allied to a similar long-distance trade network in a region expanding beyond the Arabized Islamic heartlands.

Future Directions

Other than progressing the key issues and debates outlined above, there are a number of core research areas that would improve understanding of the West African Islamic past in itself and insert West African Islamic archaeology into wider global debates.

1. *The archaeology of religion*. Research on this core area of Islamic archaeology has been relatively poor. Firstly, a more systematic assessment of evidence for mosque architecture is required, including analysis of style and space, but also *qibla* orientation, and site location. In addition, it is necessary to use the available evidence, particularly from epigraphy, to communicate early conceptions of Islam among West African populations, the epigraphic corpus in itself containing numerous Koranic passages and other Islamic lore and local renderings of these. Surface remains from burial grounds also offer a fascinating resource, including funerary stelae, enclosures, and monuments. Existing excavated burial evidence is also important (e.g., Gronenborn et al. 2012; Paris 1996), particularly for what this shows about crossovers between animism and Islam.
2. *Secular architecture and settlement planning*. So far a synthetic and analytical understanding of the secular built environment of Islam in West Africa is less developed even than understanding of religious architecture. There is in fact a relatively wide range of evidence, particularly from the northern Sahelian stone towns, not only from excavated data but also from aerial photographs. This aerial photography also represents an ideal resource for thinking about settlement planning of Muslim towns. This certainly requires engagement with the extensive work done by art historians and anthropologists.
3. *Locally produced material culture*. It has already been stated how little archaeologists have generated insights into locally produced Islamic material culture in comparison to their insights into imports. Anthropology has begun to gain certain detailed insights into how pottery making and technical style, as well as form, changes with Islam (O. Gosselain personal communication), and therefore this represents a potentially ideal point for archaeologists to commence.
4. *Diet*. While archaeology is well equipped to deal with this crucial topic due to the widespread preservation of bones and botanical

material, as yet a systematic treatment has not been attempted. Recovery of evidence at Tadmekka provided positive signs of the potential of investigation, including unexpected evidence of dog and wheat consumption (Nixon 2009).

5. *Cross–Saharan connections*. Throughout the majority of its history, West African Islam has been closely linked to other distant parts of the world and in particular had a strong history of interchange with North Africa. Given this, it is somewhat surprising that there is an almost total lack of archaeological exchange across the Sahara. This is not only an issue for studies of trade goods and immigrant communities as there were important episodes within African Islamic history which involved both North and West Africa. Most obviously, the Almoravid movement came from Mauritania to conquer Morocco and Spain. Also, early Ibadi culture spanned the Sahara, and the Fatimids had major involvements with West African trading towns. Lastly, in the late sixteenth century, it is impossible to consider West African history without the Moroccan conquest, and likewise this movement left impacts and archaeological remains in Morocco.

In addition to new research themes, there are innumerable important Islamic sites that have never been investigated, from Chinguetti in Mauritania, referred to locally as "the seventh city of Islam," to the early Songhay capital town of Kukiya, to the Kawar oases in Niger where some of the first Islamic populations in West Africa settled. Also, there is the rarely discussed and underexplored Senegal river zone (see McIntosh et al. in press). This is not withstanding the as yet undiscovered capital cities of the states of Ghana and Mali whose kings were some of the most important converts to Islam. The archaeology of Islam in West Africa has already provided many insights, but in some ways the surface has hardly yet been scratched. When and how this is explored further certainly though relates to larger patterns of international politics and currents of Islam in West Africa.

West Africa: Museums

Deborah Lindsay
College of Humanities, Arts and Social Sciences, Flinders University, Adelaide, SA, Australia

Introduction

West African museums are as diverse as West African cultures. They include history museums, research institutes, open-air museums, privately owned museums, and religious sites. Major influences on the type, size, and constitution of the

West Africa: Museums, Fig. 1 Map of West Africa (Map drawn by Kylie Lower). (Source: United Nations 2005)

museums include factors such as remnant or sourced artifacts and collections, religious prominence (Islam, Christianity, and African traditional religions), and the availability of financial support. A common thread is the display of vibrant and dynamic cultures.

While the treasures and artifacts of West Africa are routinely displayed in the museums of former colonial powers, such as the British Museum in the United Kingdom and the Ethnologisches Museum in Germany, support is needed to protect, conserve, and display the collections held by museums in West Africa itself.

Definition

The Sahara Desert to the north borders the region of West Africa while the Atlantic Ocean borders the western and southern areas of the region. The region of West Africa includes Benin, Burkina Faso, Cameroon, Cape Verde, Côte d'Ivoire, Gambia, Ghana, Guinea, Guinea-Bissau, Liberia, Mali, Mauritania, Niger, Nigeria, Senegal, Sierra Leone, and Togo (Fig. 1). The region's natural cultural and linguistic diversity was reinforced by varied influences from European colonization by the British, French, German, and Portuguese. Accordingly, there is great variety in both the content and form of museums in West Africa.

Key Issues and Current Debates

The key issues for museums in West Africa concern the professional training of staff to curate artifacts and prepare exhibitions, obtaining

sufficient funding to conserve and protect materials and dealing with the legacies of colonialism, including the repatriation of materials from former colonizing countries.

While some people had accompanied archaeologists on fieldwork or were employed as cleaners or attendants at museums, until recently, few curators in West African museum had undergone professional training in museum management skills. The lack of trained staff and dedicated funding to manage and analyze collections, and undertake training and educational programs led to many museums failing to develop a vision or mission consistent with national goals (Ardouin and Arinze 2000).

The Bendrologie Museum of Manega in Burkina Faso provides an example of a private museum that has successfully integrated local cultural traditions into museum displays. This museum has three functions: collection, conservation, and the study of art objects. Several buildings are used for exhibitions, while others are administrative. In addition, the museum houses dwellings built using traditional techniques, including Bobo, Senufo, and Fulbe houses. The museum's collections include masks, musical instruments, weapons, tombstones, books, paintings, currency, jewelry, and over a hundred stuffed animals (Ardouin and Arinze 2000: 65–66). One of the interesting places in the Museum is "The Pavilion of Death," which houses objects and displays relating to death. When visiting this space, visitors must enter and exit backward, and remove their shoes and hats, in deference to Mossi cultural customs regarding death, death being the opposite of life (Bendrologie Museum of Manega 2013).

Though funding is a major issue for museums throughout Western Africa, the establishment of the African World Heritage Fund in 2006 provided an additional source of revenue for protecting and conserving those museums that are located on World Heritage sites in West Africa.

Two of the 32 places from West African countries inscribed on the World Heritage List in 2013 are museums. These are the Royal Palace of Abomey in Benin and Old Towne of Djenné in Mali. The Royal Palace of Abomey is the remnants of a vanished kingdom, which ruled from 1625 to 1900 (Fig. 2). The world heritage area is inclusive of 10 palaces, which are no longer inhabited. Two of the palaces were restored to house a collection of royal objects. The Historical Museum of Abomey illustrates the history of the kingdom and its desire for independence against colonial occupation. The collection is used in exhibitions and educational programs and includes murals, sculptures, and a series of intricate earthen bas-reliefs (Ardouin and Arinze 2000: 164; UNESCO 2013b). The Old Towne of Djenné is one of the oldest towns of sub-Saharan Africa, being inhabited since 250 BCE. Around 2000 traditional houses have survived. The houses are built on hillocks to protect them from seasonal floods (Fig. 3). This place is an open-air museum that includes public buildings and family dwellings. Excavations have discovered remains of traditional brick structures (djénné ferey), funerary jars, millstones, and various terra cotta artifacts. The buildings are earthen construction and include several monumental houses, the reconstructed Great Mosque, Koranic schools, and the Tombs of the Saints (Ardouin and Arinze 2000: 24; UNESCO 2013a). Though families normally have a duty to maintain their architectural heritage, at Djenné family dwellings are in a poor state due to internal conflicts and disputed successions.

The West African Museums Programme (WAMP) started in 1982. WAMP is an African nongovernment organization dedicated to the development of private, community, specialized, and public museums in West Africa. Its mission is to improve the capabilities of museum professionals and organizations and increase attendance at museums in West Africa, regardless of language and geographical barriers. WAMP organizes various training opportunities, such as workshops, courses, symposiums, and regional programs. WAMP has individual and institutional membership (WAMP 2007). WAMP has hosted several major workshops focusing on different

West Africa: Museums, Fig. 2 Old Towne of Djenné. (Source: Stephen Davies)

West Africa: Museums, Fig. 3 Royal Palace of Abomey. (Source: Stephen Davies)

themes. The first workshop in 1985 in Lomé, Togo was on "Museums and the Community in West Africa." This was followed by "Museums and Archaeology in West Africa" in Abidjan, Côte d'Ivoire, in 1993, "Museums and History in West Africa" in Ouidah, Benin, in 1995 and "Museums and Urban Culture in West Africa" in Accra, Ghana, in 1996. WAMP has a website (WAMP 2007) and various publications such as a regular Bulletin, books, videos, and audios. In 2000, WAMP published a *Directory of Museums in West Africa*, listing the museums by country and type. The proceedings of the above major workshops have also been published. Arinze (1988: 37) advises that WAMP has played a positive role for stimulating more representative collections and the establishment of more local museums. The Small Grants Programs run by WAMP has also been successful in stimulating practical activities in museums.

Future Directions

The establishment of many museums during the colonial era in West Africa served the colonial agendas of the time, particularly that of articulating the devolution of political authority with building more modest reforms through progress in education (Hargreaves 1996: 107). From the 1950s, museums were used as a mechanism to rewrite history and in fostering national consciousness. Efforts were made to train Africans to work in museums. Governments started to take responsibility for museum funding. In 1963, UNESCO established a training center in Jos, Nigeria, which trained many museum professionals (Arinze 1988: 32).

The repatriation of cultural objects has long been a matter of concern for museums in West Africa. Throughout West Africa, objects of movable heritage have been plundered from archaeological sites, due to a lack of local awareness and unregulated tourism. Indeed, Basu (2012: 163) argues that one of their primary flows of antiquities is into European and North American museums and art markets. The most renowned repatriations in more recent times include the repatriation of the Benin Bronzes to Nigeria (O'Neill 2004).

Dealing with the legacies of colonialism is a challenge for museums throughout West Africa. In the postcolonial era, one response has been to neglect the parapets of colonialism, including museums. In Sierra Leone, for example, Basu (2012: 146) argues that the neglect of the National Museum in the postcolonial era can be regarded as intentional, as a "tacit act of resistance against the hegemonic forces of colonialism, against even the memory of colonialism."

Throughout West Africa, museums are adopting different models to present interesting and new experiences. Various mechanisms have been set up to tackle issues surrounding museum management. For instance, at Djenné, surveillance teams were set up to fight unauthorized excavations of archaeological sites and an information and awareness center was established to educate visitors to the city (Ardouin and Arinze 2000: 27). Although they may share similar goals of social inclusion and righting historical wrongs, the approach taken to museums in other countries that portray African heritage and culture is a contrast to the approach taken within African museums, the latter which is more empowering to Africans (Oldfield 2012).

One critical issue facing West African countries today is that of reclaiming and curating their pasts. For some museums, the priority is to undertake further research into identified or unattributed objects in their collections, while for others, there is a need to prepare interpretative materials for visitors or conserve their collections. Irrespective of the issues faced by each individual museum, it is clear that museums in West Africa have an important role to play for international visitors, visitors from different parts of Africa, and nationals of the particular country.

West and Central Africa: Historical Archaeology

Neil Norman
Department of Anthropology, College of William and Mary, Williamsburg, VA, USA

Introduction

The region of West Africa – extending from Senegambia in the west to Cameroon in the east and bordered by the Atlantic Ocean in the south and the Sahel to the north – is ripe for archaeological research focused on early global interactions. In the mid-fifteenth century CE, notable European figures, such as Christopher Columbus, navigated along the West African coast and exchanged ideas and goods with speakers of the Niger-Congo language, who dominated local political relations (DeCorse 2001: 3). Likewise, the region of Central Africa – encompassing the area in, and between, the states of Cameroon, Chad, and the Democratic Republic of the Congo – offers a prime setting in which to investigate the emerging relations between fifteenth-century CE Portuguese traders and Bakongo. Researchers who engage in historical archaeology in West and Central Africa use methods and theories aimed at elucidating the intense interconnectedness that defines modern life. Yet, absolute definitions of the term are impossible and debates rage over the moment marking the start of the historic era and the relative agency exerted by African groups and outside ones.

Definition

In early programmatic statements, historical archaeology was defined by the expansion of Western European people across the globe and attendant social, economic, and political changes experienced by the non-European groups they encountered. Americanist researchers set the pace for such theorizations and looked to the mid to late fifteenth century as the period when

West and Central Africa: Historical Archaeology, Fig. 1 View of Elmina Castle from the sea in 1745–1747 (Astley 1745–1747: vol. 2, plate 61, facing p. 589)

explorers connected continental Europe to the broader Atlantic World. In turn, they distinguished historical sites as ones where archaeologists could intermingle European lines of evidence such as artifacts, settlement patterns, aesthetic qualities, and documentary sources to measure the frequency and amplitude of local changes. Early historical archaeological efforts in West and Central Africa followed Americanist research paradigms and focused on European monumental architecture and political prominence (Posnansky and DeCorse 1986). Thus, stone trading forts along the Ghanaian coast and colonial buildings in Angola served as benchmarks for European dominance in local political arenas (Fig. 1). Researchers used a similar investigative frame to interpret archaeological sites associated with Arab traders, who were in the Sahel of West Africa by the end of the first millennium CE. In both cases, sites associated with outside groups were associated with literacy and urbanism, while sites associated with local groups were interpreted as nonliterate, prehistoric, and village or town dwellers.

More recently, researchers have critiqued definitions of historical archaeology underpinned with Eurocentric notions of cultural exchange and the omission of African oral testimonies as a valid line of comparative evidence (Andah and Okpoko 1979). The subdiscipline has been further broadened by questioning the assumption that European/African power dynamics associated with colonialism were analogous to those in the deeper historical past (Cusick 1998; Lane 2005). Rather than a focus on the impact of Europeans, these more holistic efforts now theorize Europeans as intrusive and part of a broader historical process through which outside traders and diplomats were seamlessly integrated into local negotiations of power and authority. Research paradigms accordingly shifted to understand the long-term historical processes impacting local political economies and the ways that Europeans were latecomers to such interactions (Stahl 2001). Africanist researchers are still at pains to define the "historical" element of historical archaeology. Rather than attempting to define fixed moments in the past where history begins and prehistory ends, Africanist archaeologists argue that interpretations of the past are constructed in the present. Thus, the past and timelines dividing it are products of modern political negotiations and the agendas of individual researchers (Reid and Lane 2004). Despite its arbitrary and political nature, historical archaeology provides a means of drawing West and Central Africa into debates over modernity, cosmopolitanism, and globalization. While the earliest examples of historical archaeology in West and Central Africa highlighted the presumed political sea change caused by European interlopers, more recent projects focus on placing events associated with European contact and colonialism along a much longer historical arc.

Key Issues

Current longitudinal studies do not assume that West and Central Africa are on an evolutionary trajectory toward a Western prototype. The investigation of African urban forms nicely illustrates this point. McIntosh and McIntosh (1995) convincingly argue that cities emerged in the Middle Niger Delta region in the late first millennium CE. The urban forms, at sites such as Jenne-jeno, predate the entrance of European and Arab traders into the area and exhibit unique kinds of settlement types and political arrangements. Rather than a palatial citadel surrounded by an urban warren, Jenne-jeno exhibits a massive town wall surrounding individual urban clusters, each of which contains house compounds similar in size and appointment to one another. This heterarchial arrangement of structures does not fit standard models of urbanism in other parts of the globe where cities are often found nested within hierarchical settlement systems and contained within state-like political systems. Roderick McIntosh uses the Jenne-jeno example, alongside ethnographic and linguistic research in the surrounding region, to explore the deep symbolic reservoirs contained within the modern oral histories. He argues that these accounts hold the key for understanding how archaeological actors actively manipulated their local environments and then passed along detailed knowledge of landscapes to future generations. Moreover, he questions whether or not it is necessary for a city to be supported by a state-like political structure. Indeed, it appears that dense arrangements of people – urban centers surrounded by related rural countryside – were possible in the Sahel without the support of broad state-like political interactions.

While the McIntoshes focused on recreating the dynamic relationships connecting Jenne-jeno to its nearby hinterland, Timothy Insoll (1997, 1998) has documented the trans-regional networks that connect Timbuktu and Gao. Through archaeological survey and detailed mining of local Arabic archives, Insoll has traced the vibrant trade networks that moved gold, salt, ivory, and war captives between the Sahel, North Africa, and the broader Mediterranean region (see also Haour 2011). Attempts to connect local political economies to trans-regional ones is a classic research agenda in the historiography of historical archaeology, as is creating social biographies of trade goods. David et al. (1991) used a detailed ethnoarchaeological investigation of local handbuilt earthenware ceramic vessels to reveal the ways that material culture frames ethnicity and identity in present-day Cameroun. Analogous decorative styles and depositional patterns in the archaeological record suggest that similar dynamics were at play in the deeper archaeological past. In a similar vein, Akin Ogundiran (2002) has investigated the shifting regimes of value associated with cowry shell "currency" used across West Africa. This study traced cowries from the Maldives Islands and into shrines, ancestral offerings, and ritual regalia.

Whereas documentary sources, such as ship's manifests and diarist's accounts, discuss cowries in economic terms, Ogundiran demonstrated that Yoruba oral sources and modern ethnoarchaeological observations can broaden the interpretation of cowries into social and political realms as well. Furthermore, his study illustrates the utility of addressing issues of the Atlantic World at both local and global scales of interaction. Gouda and English pipe makers, who created the iconic white clay pipes ubiquitous on Atlantic era sites, never intended for their wares to be included in Bight of Benin ancestral shrines (Norman 2009). Granular histories, which work from the specific domestic contexts up to instrumental transnational ones, hold the potential to challenge conventional interpretations underpinned by Western European notions of materiality. The interpretation of cowries and pipes in West Africa has been modeled on the work of Ann Stahl (2001), who suggests working "upstream" from the present to the deeper archaeological past. Stahl's longitudinal research project began with intensive ethnohistorical and archaeological research conducted with people living in and around the site under investigation. These oral sources were then carefully compared, and contrasted, with archaeological material sequenced from the present to the Iron Age. Through identifying tensions between oral,

documentary, and archaeological sources, Stahl elucidated the changes in aesthetic preferences and daily practices as the Banda region of Ghana was drawn into regional urban networks and Atlantic spheres of exchange.

As the above examples illustrate, archaeologists in West and Central Africa regularly push the bounds of the "historic" into what once was considered the deeper "prehistoric" past. Yet for this broad region, historical archaeology remains synonymous with the investigation of the emerging Atlantic World and the dislocations associated with colonialism. Attempts to understand the African Atlantic or colonialism must address the forced removal of approximately 12 million people from West and Central Africa to slave societies in the Americas. In return, tons of mass-manufactured trade items from Europe, tobacco from the Americas, and cowries from the Maldives poured into the area. Due to the global reach of trade associated with war captives on the African coast, there is a long-standing research agenda of integrating West and Central Africa alongside related locales of the African diaspora as one unit of analysis (Agorsah 2011). Merrick Posnansky was one of the first researchers to initiate research on the coastal West African states that profited from the Atlantic slave trade. Kings and elites associated with the polities of Allada, Dahomey, and Hueda (Fig. 2) controlled coastal outlets into the Atlantic and in turn taxed traders and used the surplus to lavish gifts on political followers (Norman 2009). Amassing such "wealth in people" fits within local understanding of power and authority, which involves mobilizing people, rather than specie. Although each of these polities experienced population expansion and settlement nucleation inward toward their central palace complexes, archaeological research reveals that political structures, economic networks, and social processes were expanded rather than radically altered during the Atlantic era. The investigation of interregional and intraregional relationships between West African states has brought into clearer focus the massive movement of people and things away from the Sahel in the fifteenth and sixteenth century and toward the coast. It has also provided poignant vignettes of people in smaller-scale sites and border regions, who were caught between larger warring states and buffeted by demands for war captives (Usman et al. 2005).

As with the emergence of urbanism and transregional trade, researchers vigorously debate the origins of slavery (see Lane and MacDonald 2011). Questions emerge over whether enslavement – as a political designation where one person, or group of people, forcibly claims ownership of others – represents an internal or external phenomenon. As discussed above, heterarchy appears to be a common political arrangement in at least some areas of West and Central Africa. At the same time, hierarchial political arrangements where political leaders collect wards, concubines, political captives, and pawns appear to have a deep history throughout the region as well (e.g., Swanepoel 2011). Researchers are thus faced with the problem of how to identify enslavement in the archaeological record. At the level of the domestic unit – house or palace compounds – identifying enslavement appears problematic. The houses of "free" rural agricultural and enslaved laborers might present very similar archaeological signatures. Given that West and Central African leaders often circulated material wealth, rather than amassing it themselves, identifying the residences of elite African "slave owners" presents problems as well. Most researchers turn to broader landscapes as a means of identifying regional level warfare and intensive agriculture that may represent the results of slaving as a political strategy.

Increasingly, historical archaeologies of West and Central Africa draw on landscape studies in an attempt to highlight the active role that monuments, spaces, and places play in the human experience (Monroe and Ogundiran 2012). Such studies have been particularly successful in engaging the interests of local stakeholders through research efforts focused on local concerns (Apoh and Gavua 2010). Landscape studies also work to disrupt conventional narratives focused on European agency associated with the built landscape. Brempong Osei-Tutu (2007) demonstrates that, while massive, European forts can be fonts of memories documenting the dislocations associated with European trade and colonialism.

West and Central Africa: Historical Archaeology, Fig. 2 View of the Huedan palace complex at Savi in 1745–1747 (Astley 1745–1747: vol. 3, plate 9, facing p. 64)

Future Directions

It should be noted again here that no unifying theoretical, methodological, or chronological definition for historical archaeology exists for West and Central Africa. Yet, researchers working on sites from c. 1000 CE to the twentieth century commonly focus on the ways that relentlessly interconnected lives impact people at local and global scales of interaction. The robust interplay of landscape, material culture, documents, oral sources, and archaeological material is a common – but not universal – research design for such projects. In terms of theory, many recent historical archaeology studies of West and Central Africa embrace a critical stance where researchers acknowledge their own place in global politics; the history of colonialism, enslavement, and racism; and the scarcity of African researchers. Indeed it is surprising that the amount of research by African diaspora researchers in the Americas (e.g., Fennell 2007) on the Bakongo region dwarfs that generated by Africanist researchers. Moving forward, it seems necessary for greater direct collaboration between researchers in the Americas, Caribbean, and Africa. These research strategies should include multisited projects that document the forced removal of specific groups, or individuals, into the Atlantic World as well as the ways that they reconstituted life in diasporic places. Nonetheless, historical archaeological projects in West and Central Africa need not recreate the dynamics of colonialism, where research designs and project funds are controlled by outside groups. If historical archaeology is to embrace calls to decolonize the discipline, it is clear that African researchers require an interpretive space to put forward their own narratives of the past, funding to make projects possible, and universities from which to foster local dialogs. Perhaps (re)awakening local interests is the key for historical archaeology to thrive in West and Central Africa and archaeologists should, as Robertshaw (2004) suggests, adopt storytelling to fit with the regional aesthetic for passing along important knowledge about one's past.

State of Knowledge and Current Debates

Introduction: Sub-Saharan Africa and the Elusive Notion of the Neolithic

The very concept of the Neolithic on the African continent is the subject of considerable debate, as is highlighted in the introduction of the collective work *The Archaeology of Africa*: *Food*, *Metals and Towns* (Sinclair et al. 1993). The definition of the Neolithic, originally designating the presence of polished stone tools, has rapidly been enriched by association with the presence of ceramics and especially the concept of a transition from predation to production, thus resulting in a very broad definition used at once to define chronological stages and cultural entities (Sinclair et al. 1993). The classic concept of the Neolithic is in fact articulated around the appearance of economies of production (livestock, farming), involving the settlement of populations and the development of some technical innovations (grinding equipment, ceramics). While, broadly speaking, this schema corresponds particularly well to the situation known in Europe, it is not at all applicable under the same form to the African continent, where ceramics, agriculture, livestock, and settlement appears independently, with more or less important differences in time and space according to the region. In addition, the economic systems that have developed throughout the Holocene in sub-Saharan Africa are extremely varied, making it even more difficult to define a concept better suited to the continent.

This situation is reflected in the archaeological literature by considerable terminological diversity. Although the term "Neolithic" was quite widely used by Africanist researchers until the early 1980s and its use continues today, the terms "food production," "Late Stone Age," "Ceramic Stone Age," and "Later Stone Age" have gradually become more frequently used (Sinclair et al. 1993).

Several definitions of the Neolithic have been proposed by researchers working in West Africa. R. Vernet and G. Aumassip have argued that if the Neolithic is indeed a "new attitude of man toward nature," we may use criteria other than direct evidence of agriculture and livestock and that "any new evidence of a change in thinking can be considered: new attitudes vis-à-vis the tool itself, new types of behavior, habitat structure" (Vernet and Aumassip 1994: 255, editor's transl.). As a major technical innovation, the appearance of pottery constitutes a real change in the relationship between man and his environment, and some authors consider its presence as a sufficient criterion for discussing the Neolithic. The definition of an "African Neolithic" has also been suggested out of archaeological and ethno-archaeological reflections based on West African actualistic examples (Huysecom 2012). Within this definition, the term Neolithic is applicable to societies possessing a control of the environment through transformation and presenting at least one of the particularities often associated with Neolithization, whether livestock, agriculture, ceramics, or settlement. The precise establishment of a group's lifestyle from the archaeological material being often the problem, the author recommends the use of the term African Neolithic to design all cultural groups associated with the presence of ceramics and before the onset of metallurgy. S.K. McIntosh (2001) defined a "West African Neolithic" as characterized by the transition to economies of production (agriculture and livestock), succeeding the

"West African Late Stone Age" and preceding the "West African Iron Age." The presence of ceramics is thus not taken into account in these definitions. S.K. McIntosh, however, states that the sites attributed to the "Late Stone Age" with a production economy and Neolithic sites with the presence of livestock can be contemporary, just as sites with a production economy with or without the presence of metal can coexist in the same chronological range. The terms Neolithic and Iron Age, generally considered to be directly successive in time, thus do not imply a chronological independence in West Africa (McIntosh 2001: 323).

The term Neolithic is also used in Central Africa. In Gabon, an "Early Neolithic" beginning in the late 3rd millennium BCE and a "Late Neolithic" between the end of the 2nd millennium and the middle of the 1st millennium BCE have been described in this way (Clist 2005; Oslisly and White 2007). The criteria defining a Neolithic village in Gabon are notably the presence of polished stone tools, ceramics, grinding equipment, and pit dumps ranging chronologically between the Late Stone Age and the Early Iron Age (Clist 2005). In Central Africa, we should also note the use of the "Stone to Metal Age" concept (or SMA), corresponding to a transition period between "Late Stone Age" occupations and the appearance of metallurgy (de Maret 1995), which could be considered as another appellation of the regional Neolithic (Oslisly and White 2007). The Neolithic/SMA in Central Africa refers to a period corresponding to the appearance of ceramics and the development of new subsistence strategies, which varies from a chronological perspective in terms of the geographic zones considered, but is mainly included between the end of the 3rd and the beginning of the 1st millennium BCE.

We therefore note considerable variability in the concepts, which essentially can be explained by geographic, environmental and chronological factors. When it is used, the term Neolithic, however, often refers to the appearance of economies of production, either the presence of livestock or agriculture. Some cultures characterized by the early presence of ceramics or the exploitation of wild grasses were also considered as representatives of an Early Neolithic, appearing on the current borders of the Sahara and the Sahel at the beginning of the Holocene around 10,000 BCE, (Huysecom et al. 2009; Huysecom 2012) (Fig. 1). In Africa, the production of pottery is indeed a phenomenon appearing independently from the domestication of plants and animals. The development of ceramics was probably facilitated by the exploitation of new resources, becoming available at the beginning of the Holocene with the extension of tropical grasslands rich in edible grasses over previously barren areas (Huysecom et al. 2009). Although the appearance of ceramics thus seems connected to a type of open environment, we observe its early and occasional presence several times during the mid-Holocene in southern areas of West or Central Africa, at least partly in relation with some northern cultural groups. Pottery remains from the SMA 1 dated from the 7th/6th millennium BCE at Shum Laka (Cameroon) could thus reflect the southern displacement of populations used to exploiting savannah environments or savannah-forest mosaics following the climatic deterioration occurring toward the end of the seventh millennium BCE (de Maret 1995; Lavachery 2001) (Fig. 1). Ceramics dated to the 6th millennium BCE in Konduga (Nigeria) indicate the occupation of savannah woodland environment or forest on the old southwest banks of Lake Chad, presumably by populations originating from eastern central Sahara in search of a more favorable environment (Breunig and Neumann 2002) (Fig. 1). Although the early appearance of ceramics at Shum Laka seems to be linked to the beginnings of the exploitation of some oil-producing fruit trees (Lavachery 2001), the phenomena described above are attached neither to the appearance of domestic species nor to real settlement phenomena and do not constitute in any way a Neolithic in the classical sense of the term.

Livestock and especially agriculture involved only very late, and sometimes only temporarily, forest areas (Mbida et al. 2000; Neumann et al. 2012a). It is thus logical that the term Neolithic is used less frequently by researchers working in southern zones of West Africa as well as Central Africa. Nevertheless, it is crucial to highlight the

existence of an important common point in the history of subsistence modes in both regions. In these variable environmental, cultural, and chronological conditions, we observe the development throughout the Holocene of economic strategies based on the more or less intensive exploitation of nondomestic resources; these systems continued after the introduction of agriculture, and most of them are still operating today (Kahlheber and Neumann 2007). During the Late Holocene, between 2500 and 500 BCE, agriculture, moreover, occupied a secondary place in the mosaic of subsistence strategies, and we thus find ourselves in a general context of a "low-level food production" economy (Smith 2001), the first large, truly sedentary farming communities appearing only during the Iron Age, from the 1st millennium BCE but mainly during the first millenium AD (Kahlheber and Neumann 2007). This economic particularity is no doubt one of the main factors

explaining the problems linked to the use of the term "Neolithic" in Africa.

Although the classic concept of Neolithic consequently seems inadequate to describe the history of Holocene economic systems in sub-Saharan Africa, important changes in terms of the relationship between nature and societies occurring since the Early/Middle Holocene have motivated some authors to define an Early Neolithic beginning around 10,000 BCE. From around 2500 BCE, the Late Holocene is then characterized by the rapid expansion of pastoralism and agriculture south of the Sahara, and thus the development of real strategies for production, motivating the use of the term Neolithic by a large number of authors. In recent decades, the suffix "Stone Age" is, however, often used to refer to all cultures before the onset of metallurgy. Finally, although there is no concept to synthesize the economic and technical diversity observed for the Holocene in West and Central Africa, the majority of regional definitions, whether or not they use the term Neolithic, refer to the existence of a more or less extended period before the beginning of the Iron Age characterized by the development of new subsistence strategies involving increased use of wild resources and/or the presence of domestic animals.

Environments and Subsistence of the Late Holocene in West and Central Africa

The Appearance of Livestock South of the Sahara

Livestock was introduced in West Africa from the central Sahara through migrations influenced by the end of the climatic optimum of the Early/Middle Holocene and the establishment of more arid conditions. The movement may have begun between 5300 and 3500 BCE with the progressive abandonment of the eastern Sahara in favor of safe havens and the beginning of seasonal transhumance of pastoralists (Jousse 2004; Kuper and Kröpelin 2006). This first wave of introduction of domestic species in West Africa, with the arrival of beef, caprines, and also certainly dog, occurred between the 3rd and 2nd millennium BCE. Men and animals thus migrated together (Linseele 2007). The impact on the environment of more arid conditions from the Late Holocene, in fact, made previously unfavorable areas progressively more accessible for pastoralism. Until about 2000 BCE, the conditions favorable to the presence of the tsetse fly, transmitting trypanosomiasis (sleep disease), would have been maintained in the Sahel region which was therefore unsuitable for livestock keeping (Smith 2005). Southern regions and more particularly forested zones consequently remained adverse to farmers. The first evidence of domestic fauna in Central Africa occurs in fact very late, the oldest known dating to the 1st millennium BCE (Mbida et al. 2000).

It is possible that, during their southward migrations, nomadic pastoralists who came from the Sahara were able to move by adapting their transhumance strategies to minor ecological changes, albeit moving quickly over long distances in case of severe drought (Linseele 2007). Clearings, leading to a gradual consolidation of areas on the boundary of the endemic tsetse area, also probably accompanied the spread of pastoralism southward. The colonization of the Sahelo-sudanian zone by livestock farmers may have also assisted the rapid appearance of breeds of cows tolerant to trypanosomiasis, contributing in turn to boost the expansion of livestock. In central Ghana, bones of small size cows dated to the beginning of the 2nd millennium BCE have indeed been interpreted as representative of possible ancestors of the current N'dama cow, capable of living and reproducing in environments where the tsetse fly is found (Gautier and Van Neer 2005) (Fig. 2). This hypothesis considers that bovines of Saharan origin were able to rapidly acquire a smaller size by adapting to the more humid southern regions. The forested zones logically remain unfavorable to the presence of livestock farmers, and the remains of domestic fauna from the 1st millennium BCE are associated with a period of high climatic and environment disruptions resulting in the opening of the landscapes in forested areas (Mbida et al. 2000; Neumann et al. 2012a, b).

West and Central African Neolithic: Geography and Overview, Fig. 2 Cartographic representations of the principal cultural and economic phenomena during the Late Holocene in West Africa and Central Africa. *1* Southern limit of agriculture (pearl millet). *2* Southern limit of herding. *3* Pit sites in Central Africa. *4* Exploitation of oily fruit trees. *5* Zones with little or no documentation. *A* Saharan cultural influences. *B* West–east Sahelian cultural current. *C* East–west Sahelian cultural current. *D* Sudanian cultures. *E* Cultures of the Late Neolithic in Central Africa. Chronology in calendar years BCE

The Emergence of Agriculture in Sub-Saharan Africa

The emergence of agriculture in sub-Saharan Africa corresponds to the beginnings of pearl millet cultivation. Belonging to the Poaceae (grass) family and to the Panicoideae subfamily, pearl millet is ecologically and physiologically adapted to dry conditions in the semiarid zones of sub-Saharan Africa and is characterized by a rapidly growing cycle and a capacity to grow with annual precipitations of only 250 mm. The quantity but above all the seasonal distribution of precipitations characterizing the climate of savannahs are thus ideal for its cultivation (Kahlheber and Neumann 2007).

The oldest known remains of domestic pearl millet were discovered in the northeast of Mali, in the low valley of Tilemsi, and dated between 2500 and 2000 BCE (Manning et al. 2011). The presence of pearl millet at the Sahara-Sahel limits around 2500 BCE implies that the zone of its domestication was certainly situated further away in time and space. Hypothetic centers of millet and sorghum domestication have been

placed by J.R. Harlan (1971) to the east of Lake Chad and in the West African Sahel, based on the current distribution of their wild ancestors, but this certainly extended further north during the humid phases of the Holocene. The appearance of agriculture in sub-Saharan Africa is thus unlikely to be due to local domestication of wild plants by hunter-gatherer societies, and millet culture was probably developed by groups of Saharan pastoralists who adapted to the new environmental and economic constraints around the end of the Middle Holocene (Neumann 2003, 2005; Ozainne 2013). It is certainly a desire for the predictability of the availability of resources and thus for greater security in the supply of food which was the main generator for the domestication of plants (Marshall and Hildebrand 2002).

After its appearance in the south of the Sahara in the 3rd millennium BCE, agriculture rapidly spread through the whole of the Sahelo-sudanian zone in West Africa (Fig. 2). Pearl millet has thus been well documented since the beginning of the 2nd millennium BCE in southeast Mauritania, in eastern Mali, and northern Burkina Faso but equally more southerly in northern Ghana (Kahlheber and Neumann 2007). The culture of millet is then documented in northeast Nigeria, in the Lake Chad Basin since the final centuries of the 2nd millennium BCE, and then in central Nigeria since the beginning of the 1st millennium BCE. Westward, in the Middle Senegal Valley the first known remains of pearl millet also date back to the middle of the 1st millennium BCE (Kahlheber and Neumann 2007).

Remains of pearl millet dated to the second half of the 1st millennium BCE have also been identified in southern Cameroon (Eggert et al. 2006). In the same region and during the same period, the discovery of Bambara groundnut remnants (*Vigna subterranea*) has also been documented (Kahlheber and Neumann 2007). The presence in forested zones of these two species characteristic to the Sudano-Sahelian zone constitutes a special event in the history of African agriculture, contemporaneous with a period of disturbance of the tropical rainforest, due to increasing aridity and/or stronger seasonnality (Neumann et al. 2012b). In southern Cameroon, the establishment of a more pronounced dry season after 400 BCE indeed resulted in a significant disruption in the balance of the rainforest and the appearance of vegetation that could be cleared more easily, all of these conditions offering a suitable context for pearl millet cultivation. However, the presence in forested zones of this agricultural system adapted to the northern savannahs corresponds only to a single episode of about 200–400 years in the history of Central African settlement, with the forest beginning to regenerate and other types of subsistence being established during the first centuries CE (Neumann et al. 2012a, b).

Agriculture thus appears very late in sub-Saharan Africa, at least 6000 years after its beginning in the Middle East. This particular situation could in part be explained by the environmental context peculiar to the savannahs, which offers ideal conditions for the exploitation of wild plants as well as for pastoralism. The group of savannah landscapes, broadly speaking (semiarid to grassy landscapes and scrubland), is in fact an environment that abounds with animal and vegetable resources and constitutes more than 80% of the vegetation in sub-Saharan Africa, thus covering a much wider surface than other ecosystems (Neumann 2003). By offering pastoralists an ideal ground for their nomadic lifestyle that was dependent on the seasonal availability of wild plant resources, the savannahs may have been paradoxically responsible for the delay of the onset of agriculture (Neumann 2003; Smith 2005).

Pearl millet cultivation in all likelihood remained in the first instance a secondary strategy of subsistence (Kahlheber and Neumann 2007). Based on current archeobotanical knowledge, many late Neolithic groups cannot indeed be considered as being made up of real farmers, but rather as populations cultivating certain plants within a diversified subsistence strategy, including the intensive exploitation of wild plants, probably inherited from the Early Holocene, as an important component (Kahlheber and Neumann 2007; Huysecom 2012). We also observe in West Africa a mosaic of economic systems during the 2nd millennium BCE. The appearance of genuine

settlement agriculture in West Africa would only come with the Iron Age, probably from the first centuries AD (Kahlheber and Neumann 2007).

Economic Systems in Forest or Forest-Savannah mosaic zones

The impression of economic diversity in the Late Holocene is amplified by the distinct strategies that developed in the forest and forest-savannah mosaic zones, where the resources were different and where some mixed systems appeared. Central Africa and more generally the more humid zones of sub-Saharan Africa are thus more typically characterized by the development of agroforestry systems, as pastoralism was not adapted to these regions, mainly because of the presence of the tsetse fly. During the 2nd millennium BCE, we note the progressive development of the exploitation of oil palm (*Elaeis guineensis*) in the center and south of Ghana (Logan and D'Andrea 2012). Oil palm does not grow in dense tropical forest, favoring open areas and climates with a less pronounced dry season as well as high rainfall, and is currently found in the forest and savannah boundary areas but also in areas of secondary forest and zones cleared for agriculture. Sometimes interpreted as a marker for the anthropization of landscapes, the presence of this pioneer species in the archaeological record seems to have a particular climatic significance. In central Ghana, the charred macrofossils coming from the archaeological levels of sites of the Kintampo tradition represent, nonetheless, a robust indicator of relationships between populations and oil palm (Logan and D'Andrea 2012).

In Central Africa, the importance of oil palm is also demonstrated during the opening of landscapes occurring in the 1st millennium BCE (Neumann et al. 2012a) (Fig. 2). The incense tree (*Canarium Schweinfurthii*) is another oil-producing fruit tree species which was also found in Central and West Africa. Its presence is signaled in low quantities in central Ghana in the 2nd millennium BCE (Logan and D'Andrea 2012). In western Cameroon, this species has been visible since the end of the 7th millennium BCE, and its presence increased significantly between 2500 and 400 BCE (Lavachery 2001). We also find traces of it during the 1st millennium BCE at sites in southern Cameroon as well as in the southern forest zone in the Democratic Republic of Congo (de Maret 1990; Mbida et al. 2000). The hypothesis of the development of arboriculture during the Holocene in West and Central Africa has thus been put forward by several authors (Lavachery 2001; Oslisly and White 2007; Logan and D'Andrea 2012), but the presence and increase of fruit trees in archaeological records could also result from the intensification of wild tree exploitation in a degraded and semi-open environment (Neumann et al. 2012a).

In forest-savannah mosaic zones, mixed systems also appeared during the Late Holocene, with the example of the joint production of pearl millet and legumes like the *Vigna unguiculata* (cowpea) combined with the exploitation of oil-producing fruit trees (oil palm, incense tree). This type of mixed economy is demonstrated at the beginning of the Iron Age during the 1st millennium BCE in the Lake Chad Basin and in central Nigeria but could have been established since the 2nd millennium BC in central Ghana (Kahlheber et al. 2009; Watson 2010; Logan and D'Andrea 2012).

Finally, the hypothesis of the early cultivation of bananas in Central Africa remains controversial. In fact, banana phytolites (*Musa* sp.) were identified in southern Cameroon at the Nkang site, dated to the 1st millennium BCE, in an economic context of production with the presence of domestic animals (Mbida et al. 2000). Originating from South and Southeast Asia, the banana was introduced by humans in Africa in an already domesticated form, and its presence at Nkang has been interpreted as proof of the early existence of agricultural systems in forested zones, which could be the cause for the increase of villages that was documented for the same period (Mbida et al. 2000). However, the attribution of phytolites in Nkang to *Musa* and not to *Ensete*, a genre of the banana family which appeared independently in Africa, does not take into account recent criteria for morphological differentiation, and the chronological and environmental context of the site could additionally indicate the unfavorable conditions for the farming of *Musa* (Neumann and

Hildebrand 2009). The issue remains unresolved and requires the acquisition of more data.

Emergence of Food Production and Population: A General Scenario

Climatic Changes and Migrations in the Sahara-Sahel in the Third Millennium BCE

Between 4000 and 3000 BCE, the end of the humid period of the Early/Middle Holocene marked the beginning of a long-term trend of aridity. Between 3000 and 2500 BCE, pastoral populations reached the Sahel in West Africa from the east and central Sahara (Jousse 2004; Kuper and Kröpelin 2006). The opening of the landscapes in the Sahelian belt indicates a southward shift toward the vegetation zones during the same period. Pastoralist groups who progressively settled in the south of the Sahara seem to originate from several distinct cultural contexts but share common origins in the central Sahara; some among them may be linked to the origins of agriculture (Fig. 2). Pastoralists thus reached the Niger Bend from the large massifs of the Sahara, probably from the north of Mali and Niger as well as the south of Algeria. It is possible that some populations originating from the Sahara reached the Sahel zone much earlier, without in this case propagating livestock (Ozainne 2013).

The second half of the third century BCE was characterized by important environmental changes south of the Sahara, where general climatic degradation resulted in a gradual desiccation of the landscapes. The Sahelo-sudanian belt strip is thus affected by the arrival of cultural traits clearly indicating Saharan origins, including wide-mouthed pottery, often hemispherical, as well as decorations made with single or pivoting comb impressions. In Dogon Country (Mali), the Ounjougou site complex also shows the presence of ceramics between 2600 and 2200 BCE, indicating links with northeast Mali, southwest Niger, and central Sahara in general (Figs. 1 and 2). It is likely that, from this period, the Dogon Country was occasionally visited by groups of pastoralists during seasonal transhumance or in the context of reconnaissance of new territories (Ozainne 2013). Generally, in Sahelo-Sudanian West Africa, we find several examples of cultural traits of the Sahara on Late Holocene sites. This is the case, for example, for some pottery at the site of Pentenga in southwest Burkina Faso (Frank et al. 2001), as well as the lithic industry (geometric microliths and chisels) and ceramics (wavy decorations or pivoting impressions) in the Neolithic of the Cap-Vert peninsula in Senegal (Huysecom 1990; Thiam 2010). The phenomenon of shell middens, which mainly concerns the Mauritanian coast during the Middle and Late Holocene, appears on the Senegal River delta at the Khant sites, from the 4th millennium BCE (Thiam 2010). On the coast of the Guinea Gulf, in Ivory Coast, shell middens would more likely appear around the 2nd millennium BCE (Chenorkian 1983) (Figs. 1 and 2).

Between 2500 and 2000 BCE, pastoralists arrived in Mauritania, whereas the Inner Niger Delta in Mali, still too humid, certainly remained adverse to the presence of livestock. The expansion of livestock in the Sudanian zone was rapid, and pastoralists already reached the center of Ghana around 2000 BCE (Gautier and Van Neer 2005). This early southern penetration of pastoralism could explain the presence within the Kintampo tradition (Ghana) of cultural traits of Saharan origin since the end of the 3rd millennium BCE, particularly bifacial armatures or pivoted comb decorations on ceramics (Stahl 1994; Watson 2010). This Saharan heritage is, however, included within the development of a cultural ambiance which seems proper to the Sudanian and Sudano-guinean zone, asserting itself from the end of the 3rd millennium BCE (Figs. 1 and 2).

Pearl millet cultivation, which had been known from 2500 BCE at Karkarichinkat in the Lower Tilemsi Valley (Mali) (Manning et al. 2011), expanded rapidly in the Sahelo-sudanian belt from around 2000 BCE. The spread of agriculture seems linked to the development of a new "Sahelian" cultural trend, essentially characterized by the presence of pottery with a reduced opening, with simple or everted rims, and decorations of fibre roulette impressions (Ozainne 2013) (Fig. 2).

In the grasslands of western Cameroon, the "Stone to Metal Age 2" of the Shum Laka site, which ends between 2400 and 2000 BCE, is

characterized by an economy founded on hunting but also by the growing use of *Canarium schweinfurthii* seeds. Pottery associated with the SMA 2 of Shum Laka includes some Saharan attributes, particularly with decorations of pivoting impressions which were interpreted to reflect a progressive southward movement of ceramic technology from the Middle Holocene (Lavachery 2001) (Fig. 2).

Expansion of Agriculture and Cultural Diffusions in the Second Millennium BCE

During the 2nd millennium BCE, sub-Saharan West Africa was characterized by a gradual trend toward aridification, which coincides with the beginning of the impact of agropastoral activities in the Sahelian and Sudanian environments (Ballouche and Neumann 1995). Between 2000 and 1500 BCE, agriculture progressed very quickly indeed in areas favorable to the presence of pearl millet, essentially along the Sudano-Sahelian belt as well as in some specific environments of the southern fringe of the Sahara. The appearance of millet cultivators is then documented in southeastern Mauritania (Dhar Tichitt and Oualata, characterized by the occurrence of large resurgences of water), in eastern Mali (Ounjougou, Winde Koroji West), in northern Burkina Faso (Oursi Tin-Akof) but also further south at Birimi in northern Ghana (Kahlheber and Neumann 2007) (Figs. 1 and 2). In forest and forest-savannah mosaic environments of West Africa, other types of economies seem to have appeared in the same period, with notably the exploitation of oil palm (Logan and D'Andrea 2012). In Central Africa, the "Early Neolithic" in Gabon, dated between 2100 and 1700 BCE at the site of Okanda in the Ogooue valley, is characterized by the presence of pit dumps containing ceramics, but no precise data on the modes of subsistence are associated with them (Oslisly 1998) (Figs. 1 and 2). In the majority of sites of the 2nd millennium BCE, we additionally almost systematically find polished stone axes, which can be either imported or manufactured at sites relatively close to habitats, such as in central Ghana (Watson 2010).

By contrast, there are not necessarily systematic and exclusive associations between environmental contexts, types of economy, and cultural groups. The geographic distribution of the Kintampo tradition, principally represented in Ghana, is an excellent example as we find it in the savannah zone, the forest-savannah mosaic but also in the semi-deciduous forest during the entire first half of the 2nd millennium BCE (Stahl 1994; Watson 2010). In the north of Ghana, the Kintampo tradition is clearly associated with pearl millet cultivation at the site of Birimi (Figs. 1 and 2). At the central and southern sites of the country, we more often observe economies based on herding and the exploitation of non-domestic plant resources, including oil palm, with only one isolated case of pearl millet known at Boase (Gautier and Van Neer 2005; Watson 2010; Logan and D'Andrea 2012). These economic variants within the same cultural tradition could be explained either by the adoption of agriculture by a local culture or, in contrast, by the adaptation to the ecological potential of the forest of populations which have migrated from the Sahel (Watson 2010). Additionally, in central Ghana, the Kintampo tradition overlaps partially in time and space with another cultural entity named "Punpun," associated with a different material culture and type of economy. The overlapping at the same sites of these two cultures, differentiated by very distinct technical and stylistic characteristics of ceramics, was first interpreted as the succession of two populations, then as a local change in lifestyle, the Kintampo culture marking a local economic and cultural evolution with the transition to an economy of production (Stahl 1994). It was also explained as a social frontier between two contemporary groups, one of hunter-gatherers (Punpun) and the other of agro-pastoralists originating from the Sahel (Watson 2010). More generally, we observe a cultural ambiance proper to the Sudano-Guinean zone during the first half of the 2nd millennium BCE, for instance represented at the Kintampo sites in Ghana or Iwo Eleru in Nigeria (Shaw and Daniels 1984; Stahl 1994; Watson 2010) (Figs. 1 and 2).

During the first half of the second century BCE, a coherent cultural tradition seems to have also developed between Sierra Leone (Yengema, Kamabai)

and Liberia (Sopie), concerning in all likelihood Guinea and southwest Mali (Kourounkorokale) and corresponding partially with the "Guinea Neolithic" described in the literature before 1970 (Ozainne 2013).

Between 1500 and 1000 BCE, agriculture continued its progression toward the east and southeast along the Sahelo-sudanian belt and appeared in the southern Lake Chad basin (Gajiganna culture) from 1200 BCE (Figs. 1 and 2). Archaeological data attributed to the same chronological interval suggests the establishment of an important Sahelo-sudanian cultural current between Mauritania and the basin of Lake Chad. This phenomenon is well recorded at the sites southeast of Mauritania (Dhar Tichitt and Oualata), Méma (Kobadi), Gourma (Windé Koroji), and Dogon Country (Ounjougou) in Mali, southwest Niger (Kirkissoy), and northeast Nigeria (Kursakata). It is characterized notably by the rapid eastward progression of ceramic traditions with fibre roulette decorations (Figs. 1 and 2). This axis to be related to migrations and/or cultural diffusion developing along the Sahelo-sudanian belt during the 2nd millennium BCE and also in all likelihood to the rapid expansion of agriculture in the savannah environments (Ozainne 2013). The rapidity of this phenomenon was certainly enhanced by mobile seasonal lifestyles based on animal husbandry, in which pearl millet cultivation was probably first integrated as a secondary livelihood (Kahlheber and Neumann 2007). This schema thus implies a border effect more or less in line with forest environments, where other resources were exploited. The existence of mixed economic systems at the forest-savannah boundaries, but also of homogenous cultural traditions occupying several climatic zones, is nonetheless not excluded, as is demonstrated by the specificities of the Kintampo tradition in Ghana.

In Central Africa, the end of the 2nd millennium BCE corresponds with the beginning of the Late Neolithic (or the last period of the SMA, the Stone to Metal Age) which developed especially during the 1st millennium BCE with the progressive expansion of village communities in forestry zones. These Late Neolihtic sites are characterized above all by the presence of numerous pit dumps (Clist 2005; Oslisly and White 2007) (Figs. 1 and 2).

Climatic Changes and Socio- Economic Transitions of the First Millennium BCE

During the 1st millennium BCE, drier climatic conditions were recorded in sub-Saharan Africa, and several regions in the Sahel faced decreasing occupations from 800 BCE, possibly reflecting an increase in the mobility of populations (Breunig and Neumann 2002). Between 800 and 400 BCE, the opening of landscapes following climatic changes enabled agriculture to spread in more southern zones. Previously flooded areas southeast of Lake Chad (Kursakata, Mege) were occupied by pearl millet cultivators from the beginning of the 1st millennium BCE (Kahlheber and Neumann 2007). In central Nigeria, sites from the beginning of the Iron Age (Ungwar Kura) are associated between 800 and 400 BCE with a mixed economic system combining pearl millet and "cowpea" and the exploitation of wild oily fruit trees in mosaic forest/savannah woodlands (Kahlheber et al. 2009) (Figs. 1 and 2). Westward, the appearance of pearl millet occured later from around 800 BCE in the Middle Senegal Valley (Walalde) in an Iron Age context (Deme and McIntosh 2006).

During this period we observe the persistence of cultural currents on an east–west axis along the Sahelo-sudanian belt, and roulette decorated ceramics appeared from the end of the 2nd millennium BCE in southeast of Lake Chad Basin and in northern Cameroon (Livingstone Smith 2007). On this same axis, an inverse phenomenon could also be involved, with the appearance in southwest Niger (Kirkissoy) and in Dogon Country in eastern Mali (Nin-Bèrè 3) of some ceramic features (carinated containers, decorative geometric motifs) previously documented in northeast Nigeria (Gajiganna) between the end of the 2nd millennium and the middle of the 1st millennium BCE (Vernet 1996; Breunig and Neumann 2002; Ozainne 2013) (Figs. 1 and 2). This cultural countercurrent in the Sudano-Sahelian zone, however, is documented only by a small number of archaeological sites and needs to be confirmed. A new wave of migration from eastern central Sahara

may also have occured at the beginning of the first millennium BCE (Ozainne 2013).

In West Africa, the 1st millennium BCE is also generally regarded as a period of transition between the Neolithic and Iron Age, often characterized by the emergence of new cultural and technical specifications within contexts that are still essentially Neolithic. The final centuries before our era, however, are often marked by an important cultural and economic disruption, some Neolithic heritage being likely to survive within the early traditions of the Iron Age. Contemporary to the beginning of rice cultivation and the presages of urbanization in the Inner Niger Delta in Mali (Dia and Djenné-Jeno), the Faïta ceramic tradition is linked, for example, with the Neolithic of Dhar Tichitt, Oualata and Nema (Bedaux et al. 2005; McIntosh and McIntosh 1980; MacDonald 2011) (Figs. 1 and 2). Sahelian cultures from the Neolithic to Iron Age transition also appear to be characterized by rarer and more rudimentary lithic industries (Vernet 1996).

In Central Africa, we observe during the second half of the 1st millennium BCE an important rainforest disturbance, that can be attributed to increasing aridity and/or stronger seasonality (Neumann et al. 2012b). It is in this context that the presence of domestic millet is attested at the sites of Bwambé-Sommet and Abang Minko'o in southern Cameroon (Eggert et al. 2006; Neumann et al. 2012a). The opening of the forest landscape also promoted the use of oil palm and/or incense tree in the same region; the exploitation of nut trees is also attested in many other locations in Central Africa in the same period, e.g. in Gabon (Otoumbi) but also in the southwestern Congo (Tchissanga) and the Democratic Republic of Congo (Sakuzi, Ngovo) (Figs. 1 and 2).

From the end of the 2nd millennium BCE, the opening of landscapes also facilitated the dissemination of village communities southward through the forest areas of Central Africa, where many sites of the 1st millennium BCE are characterized by habitats often associated with sets of pit dumps containing charred remains and ceramics (Abang Minko'o, Obobogo, Okala). Comparable sites are also known in the south of humid forests in the southwest Democratic Republic of Congo (Sakuzi) (de Maret 1990; Clist 2005; Eggert et al. 2006; Oslisly and White 2007) (Figs. 1 and 2). During the first half of the 1st millennium BCE, the presence in Gabon (Okala, Epona) of one or many ceramic traditions characterized particularly by bilobed vases and incised or pivoting comb decorations illustrating the advance of neolithic groups through the forest, along the coast and the valley of the Ogowe but perhaps also following the ridge lines from southern Cameroon (Clist 2005; Oslisly and White 2007) (Figs. 1 and 2). The sites dated from the second half of the 1st millennium BCE then demonstrate a rapid transition between the Neolithic and the Iron Age in Central Africa. As in West Africa, this period seems to be also characterized by a decrease or loss of lithic industries, perhaps associated with the beginnings of iron tools, whose arrival, however, did not eradicate the polished stone axes (Clist 2005).

Generally speaking, it seems that the ceramic traditions at the end of the Neolithic and the beginning of the Iron Age in Central Africa integrate multiple sources including at once elements from Saharan traditions, such as pivoting imprint decorations, but also cultural groups that develop south of Lake Chad from the 2nd millennium BCE, particularly characterized by geometric designs, incisions, and carinated containers. Rouletted decorations appeared in northern Cameroon around the beginning of the 1st millennium BCE within the context of major savannah cultural trends initiated during the 2nd millennium BCE. This decoration technique however affected only marginally forest areas of Central Africa and spread to the east and the Great Lakes region along the forest boundaries (Livingstone Smith 2007).

More arid climatic conditions and the opening of landscapes in the 1st millennium BCE thus appear to have resulted in a coherent sequence of cultural and economic events. In the Sahelo-sudanian belt, we observe an increased mobility of populations in some environments but also an intensification of occupations in other environments, with notably the appearance of large settlement mounds and even fortified sites in areas previously flooded such as in the Inner Niger Delta in Mali (Dia and Jenne-Jeno) or the southern

Lake Chad Basin (Daima, Zilum) (McIntosh and McIntosh 1980; Connah 1981; Breunig and Neumann 2002; Bedaux et al. 2005; Magnavita et al. 2006) (Figs. 1 and 2). In the savannah environments, the first millennium BCE appears thus to be a period of social and economic transition, after which agricultural practices have become more extensive. After 500 BCE, the disturbance of forest areas in Central Africa coincides chronologically with the establishment of populations practicing millet cultivation as well as breeding small livestock and exploiting oil palm or incense tree. Finally, the appearance of iron is documented in most parts of West and Central Africa during the same period.

Conclusion

We may retain a general definition of the major cultural and economic changes in the Holocene in West and Central Africa according to a schema divided into three main stages. Firstly, from the Early Holocene, populations developed techniques of ceramic production within the confines of the Saharan and Sahelian zones, in the context of a rational exploitation of wild plants including the use of ground material, thus constituting a "proto-producer" period, sometimes called "Early Neolithic." The presence of ceramic and incense tree remains has moreover been signaled since the Middle Holocene in southern Cameroon. Secondly, during the Late Holocene, we observe the development of a "Low-level production Neolithic," characterized by a still partially mobile lifestyle, in which herding was very important and agriculture played mainly a complementary role, as well as the exploitation of wild plant resources. This sub-Saharan Neolithic (called "Later Stone Age," "Final Stone Age," or even "Stone to Metal Age" according to the region and the researchers) begins around the middle of the 3rd millennium BCE with the arrival of the first farmers and then the rapid development of pearl millet cultivation in the Sahelo-sudanian zone. From the end of the 3rd millennium to the beginning of the 1st millennium BCE, West and Central Africa thus present a mosaic of economic systems within which agriculture remains a secondary component. Thirdly, the 1st millennium BCE was characterized by the appearance of new domestic species and the development of large and more sedentary communities at the beginning of the Iron Age in the savannah zones. From this period of socio-economic transition, agricultural practices changed and became gradually more extensive during the first half of the 1st millennium CE.

The arrival of pastoralists south of the Sahara and then the emergence and diffusion of agriculture thus constitutes a set of events which are articulated in a consistent manner over time and space, and seem to be attached to a number of demographic and cultural phenomena, all suggestive of a "Neolithization-like" process. We first observe a general dynamic of north–south migrations coinciding with climatic and environmental changes at the beginning of the Late Neolithic. In the 3rd millennium BCE, the arrival of pastoralism in the Sahel is in fact linked to Saharan ceramic traditions, although the first cultivators seem to have initiated new cultural currents proper to the Sahel, clearly drawing their origin from the Saharan world. The period of the 2nd millennium BCE is characterized rather by a process of migrations and acculturations on a general east–west bidirectional axis, coinciding at least in part with the expansion of agriculture along the savannah zones and accentuated by partially mobile lifestyles still strongly influenced by pastoralism. To the south, forest environments probably induced an economic and cultural border effect likely to support the emergence of intermediary systems in the savannha-forest transition zones, either by the adaptation of cultivators or by the adoption of pearl millet cultivation by local populations. From the 2nd millennium BCE, the agriculture frontline progressively shifted south. Then, around the middle of the 1st millennium BCE, an important climatic threshold caused new migration from the Sahara to the Sahel as well as an opening of the rainforest of Central Africa. This latter event temporarily allowed the cultivation of pearl millet at very low latitudes and enhanced the growth of village communities in forest environments.

It remains difficult to identify possible cultural interactions between early farmers and hunter-

gatherer societies having already acquired pottery, since ceramic remains prior to the 2nd millennium BCE are very rare south of the Sahara. It is likely that populations living in more closed environments in southern zones during the Middle Holocene implemented economic systems requiring a lesser use of pottery than those developed by groups exploiting wild grasses in the Sahelo-sudanian belt, thus leaving behind only a small archaeological footprint. The rare examples of pottery in the sub-Saharan area during the Middle Holocene, moreover, often evoke the Saharan world and could represent the reconnaissance and gradual occupation of the southern regions by northern populations, occurring in parallel with the contemporary environmental changes.

West and Central Asia: Early Homo Fossil Records

Robin Dennell
Department of Archaeology, University of Exeter, Exeter, UK

West and Central Asia is an enormous territory that extends from the Mediterranean to the Hindu Kush and Pamir Mountains, and from the Indian Ocean to the southern edge of Siberia (Fig. 1). West Asia comprises the Arabian Peninsula, the Levant (Israel, Lebanon, western Jordan, and western Syria), Turkey, Iraq, and Iran. Some but not all researchers would also include the countries of the Caucasus – Armenia, Azerbaijan, and Georgia. Central Asia consists of the "Five Stans" of Kazakstan, Kryrgyzstan, Tajikistan, Turkmenistan, and Uzbekistan, and also northern Afghanistan. West and Central Asia vary enormously in their climate and relief. Climatically, they lie west of the Indian summer monsoon (apart from the Yemeni Mountains)

West and Central Asia: Early Homo Fossil Records, Fig. 1 Principal sites with hominin remains in West and Central Asia. ★ Key on main map: Dmanisi, Georgia. Central Asian sites: 1 Anghilak; 2 Teschik Tasch; 3 Obi Rakhmat; 4 Sul-ungir, Kyrgyzstan; 5 Khudji, Tajikistan; 6 Darra-i-Kur, Afghanistan; 7 Wezmeh, Iran; 8 Wusta, Saudi Arabia

and are thus areas of winter/spring rainfall, most of which is delivered by westerly winds from the Mediterranean. The Mediterranean coast and hinterland of the Levant and Turkey has the highest rainfall and mildest winters. Most of the Arabian Peninsula, the interior of West Asia (Jordan, eastern Syria, Iraq, and the Iranian Plateau), and much of Central Asia is now desert, and aridity is the key climatic variable. Rainfall varies from ca. 600 mm along parts of the Levantine coast to annual averages (over 30–40 years) of <100 mm in the deserts of the Negev, southern Israel, much of Arabia, the Iranian Plateau, and Central Asia. Consequently, it is likely that the core areas of hominin residence would have been in those areas such as the Levant, western Turkey, and the Caucasus where rainfall was highest.

Rainfall can vary enormously from year to year, so that annual averages are not particularly useful climatic indicators, particularly in desert regions, even when evaporation rates are also taken into account. Annual temperatures vary enormously, with some areas such as Arabia and Iran routinely experiencing daytime summer temperatures of >40 °C but cool (and generally frost-free) winters. Other areas, notably eastern Turkey, the Caucasus, parts of the Zagros Mountains, and Central Asia have slightly cooler (but nevertheless still hot) summers but very cold winters, with temperatures sometimes below −20 °C and deep snow.

In terms of relief, West Asia contains the Dead Sea Valley (400 m below sea level), and mountains (mainly extinct volcanoes) over 5,000 m high in eastern Turkey (Mt. Ararat, 5,165 m), the Caucasus (El'brus, 5,642 m), and northern Iran (Mt. Demavend, 5,604 m). The Zagros Mountains are a major mountain chain over 1,500 km long along western Iran with peaks over 4,000 m that divides the lowlands of Mesopotamia from the Iranian Plateau, which has an average altitude of 1,000 m. Apart from the Tigris-Euphrates river system of Iraq, Syria, and Turkey, the Orontes in Syria, and the Oxus in Central Asia, Southwest and Central Asia have few large perennial rivers. This is especially true of Arabia, which now has none, and Iran, which has only one, the Qara Su, which flows through the Zagros Mountains into the Euphrates. Availability of perennial water would thus have been a major constraint on early hominins throughout West and Central Asia. In areas away from major rivers, the main water supplies would have been lakes and springs, especially along some mountain ranges. Most of the evidence for Early Pleistocene hominins in Southwest Asia comes from the edges of extinct lakes and streams.

Climatic History

The Pleistocene climate of West and Central Asia experienced numerous small-scale fluctuations in the Early Pleistocene (2.4–0.8 Ma) between warm, moist periods and cooler, drier ones, with an average duration of 30–40 ka. Around a million years ago, there was a shift to more severe fluctuations on an average cycle of ca. 100,000 years, with longer and much cooler periods (=glaciations) punctuated by shorter warm and moist (=interglacial) periods. Since 600 ka, there have been four particularly long and severe periods when temperatures and rainfall were considerably lower than today. Throughout the Pleistocene, hominin settlement was likely centered in areas with higher rainfall and dependable supplies of water (notably the Levant) such as perennial rivers, lakes, and springs, and the most arid parts were probably uninhabited or only sparsely settled. In cold and dry periods, much of inland western and central Asia was probably uninhabited.

Role as a Cross-Roads and Corridor

Neither West nor Central Asia was a closed system that had no links to neighboring regions. The Levant in particular is often envisaged as a corridor that linked – when conditions were favorable –West Asia with Africa, Europe, and continental Asia. Western Turkey was likely the main corridor between Europe and Asia. The Arabian Peninsula was probably also a major corridor between Africa and Asia via the Sinai Peninsula at the head of the Red Sea, the 1000-mile (1600 km) coastline of the Red Sea, and the Bab al Mandab strait at its southern end. Central Asia is another open system, with potential links with North China to the east, and India and Pakistan to the southeast via Afghanistan.

Historical Background

Paleoanthropological research in West and Central Asia has been very piecemeal and low-key for the most part, and many parts remain very poorly known. The longest and heaviest concentration of research has been in Israel. The British were very active before 1939 in what was then the British Mandate of Palestine, and Dorothy Garrod from Cambridge, UK, undertook a major series of

excavations of caves such as Tabun and Skuhl. Since 1948, Israeli archaeologists have been extremely active, as have American teams, and the literature on the Paleolithic of West Asia is dominated by that on evidence from Israel. Much less research has taken place in the rest of West Asia: state-sponsored research is often overshadowed by the need to invest scarce resources on later historic sites and monuments, and major Paleolithic sites have often been excavated by foreign-teams operating under license – Ralph Solecki's excavation over several seasons at Shanidar Cave, Iraq, is one obvious example. In Central Asia, some paleoanthropological research occurred in Soviet times, such as Okladinov's excavation of the Neanderthal child's skeleton at Teschik Tasch. This tradition continued after 1989, and the late Andrei Dondonov and Vadim Ranov jointly conducted outstanding investigations of the Paleolithic and climatic record of Tajikistan. Paleoanthropological research in other countries formerly within the Soviet Union has prospered since 1989. Georgia is an outstanding example, with the 1.77–1.85 Ma evidence from Dmanisi – fortuitously found beneath a medieval castle – one of the most important discoveries in paleoanthropology from the past 100 years. At present, there are outstanding prospects for Paleolithic and paleoanthropological research across most of West and Central Asia: when so little is known, there is so much still to learn.

The Fossil Evidence for Homo in West and Central Asia

West Asia has an exceptional fossil record for our genus for the Early Pleistocene, 1.8 Ma ago (see Dennell 2009), and for Neanderthals and our species in the last 250,000 years. Sadly, there is a major gap in the fossil record between these two time-lines. Central Asia has very little fossil evidence for our genus, and only from the last 100,000 years. The earliest and most informative evidence for our genus outside Africa comes from Dmanisi, Georgia. There is also a hominin right lower incisor (UB 335) from the lake-side site of "Ubediya," Israel, that is ca. 1.0–1.4 Ma-old and attributed to *Homo* sp. indet. (Belmaker et al. 2002).

Dmanisi

The paleontological site of Dmanisi lies directly underneath a medieval castle, and over a basalt laid down ca. 1.8 Ma, during the Olduvai Subchron of normal magnetic polarity. The lowest deposits (Unit A) over the basalt contain artifacts, fossils, and stone artifacts. Paleomagnetism analysis shows that this unit has a normal polarity and was formed during the Olduvai Subchron, ca. 1.77–1.95 Ma. Shortly after 1.77 Ma, the top of Unit A was eroded and a series of cavities developed inside it. The sediments inside these cavities have a reversed polarity, and were thus formed after 1.77 Ma. These cavities contain most of the non-hominin fossils and artifacts, and two hominin crania (D2280 and D2282) that came from the same level as the mandible D211 that was found in 1991. Overlying Unit A and the cavities, there is an abrupt erosional layer along the base of some stream channels that cut into Unit A and then filled with sands and gravels (Unit B1). These channels contain artifacts, a toothless hominin cranium (D3444) (Lordkipanidze et al. 2006) and a mandible (D3900). Unit B1 is covered by an archaeologically sterile layer of sand (Unit B2) with reversed polarity, i.e., <1.77 Ma. The entire fossil hominin and associated stone tools date from and shortly after the Olduvai Subchron and are thus ca. 1.77–1.85 Ma.

The hominin remains found so far comprise five published crania, three mandibles, the partial skeleton of an adolescent associated with skull D2700/D2735, and the post-cranial remains of one large and two small adults. The crania are very small-brained: 775 cc^3 for D2880, 650 cc^3 for D2282, c. 625 cc^3 for D3444, and only 600 cc^3 for D2700, which was associated with mandible D2735 in layer B1, and 546 cc^3 for D4500. D2700 was from a sub-adult, probably male, whose head was likely at or near its fully adult size. The classification of these remains has proved problematic. There is general agreement that

they represent a very early form of our genus, with affinities to the East African *H. habilis* and *H. rudolfensis* that dispersed out of Africa between 2 and 1.8 Ma (Gabunia et al. 2000). The crania have been classified as the earliest form yet found of *H. erectus*, including those from Africa (a.k.a. *H. ergaster*). Indeed, some researchers have suggested that they may even be ancestral to *H. erectus* in Africa – in other words, some of their descendants dispersed southwards into Africa (Rightmire et al. 2006). The mandibles, however, tell a different story. Following the discovery of a robust mandible D2600, a new taxon, *H. georgicus*, was proposed (Lumley and Lordkipanidze 2006). More evidence is needed before we can choose between *H. georgicus* or a primitive form of *H. erectus*, or determine whether two populations are present. A more recent and plausible assessment is that the Dmanisi population and its contemporaries in East Africa (*H. habilis* and *H. rudolfensis*) are part of a single evolving lineage of early *Homo* (Lordkipanidze et al. 2013).

The postcranial evidence offers some fascinating insights into the anatomy of the earliest-known Asians (Lordkipanidze et al. 2007). It shows that these individuals were small, with an estimated height of only 144.9–166.2 cm, and a weight of 40–50 kg. These figures overlap with those for australopithecines (110.0–151.00 cm; 29–49 kg), earliest *Homo* (125.0–157.0 cm; 32–52 kg), and the 1.53 Ma skeleton of *H. ergaster* from Nariokotome (KNM WT15000) (150.5–169.1 cm; 45.5–70.6 kg) but are generally intermediate between australopithecines and early *Homo* on the one hand, and KNM WT 15000 and later hominins on the other. Their encephalization quotient (or EQ, the ratio of brain to body size) of 2.57–3.13 was also intermediate between early *Homo* (3.1) and KNM WT15000 (2.71–3.78). Additionally, there was an absence of humeral torsion, meaning that their hands would have faced forward instead of hanging sideways, as with modern humans, and the foot was orientated more medially than in modern humans, despite its modern arched appearance.

As might be expected for such an early form of our genus, the stone tools are very simple, and show no evidence of standardization or core preparation, as the main objective of flaking appears to have been the production of a sharp-edged flake (de Lumley et al. 2005; Mgeladze et al. 2011). The tools are most like Oldowan ones from East Africa that date back to 2.6 Ma, but because so few were retouched, they have been classified as "pre-Oldowan" to emphasize their technological simplicity. Nothing is yet known about their subsistence, although the fact that the individual D3444 survived without teeth implies either that soft foods were available or that he was fed altruistically by others who softened food for him by chewing it first.

The Big Gap in the Fossil Record: 1.8 Ma–200 ka

West Asia has been described as a "black hole of paleoanthropology" (Dennell 2009: 192) because of its lack of hominin fossil between the time of Dmanisi and the appearance of *Homo sapiens* ca. 200 ka ago, despite the excellence of its archaeological record, particularly for the Levant. Recent finds of cranial fragments from Koçabas, Turkey, and el Khown, Syria, have been identified as *H. erectus*, but in the absence of facial and mandibulary evidence, this identification is tenuous. At around 800 ka, new types of Acheulean handaxes and cleavers similar to ones in Africa were used at the site of Gesher Benot Ya'aqov in Israel, and may indicate an influx of new groups from Africa, but their identity and morphology are unknown. After ca. 400 ka, the Acheulean is followed by a very different type of tool assemblage known as the Jabrudrian (makers unknown), and this in turn was replaced by Mousterian assemblages after ca. 250 ka. In Central Asia, the earliest tool assemblages date from ca. 900 ka; these were not Acheulean, but very small flakes and were used with little change throughout the middle Pleistocene. The identity of these earliest inhabitants of Central Asia is currently unknown.

Because almost nothing is known about the type of hominins that inhabited West Asia between the time of Dmanisi and ca. 200 ka, or about Central Asia between 900 ka and the last

West and Central Asia: Early Homo Fossil Records, Table 1 Hominin remains from West and Central Asia 1.0 Ma–200 ka

Site	Age	Hominin remains	Classification
Azych, Azerbaijan	Mid-Middle Pleistocene	Mandible	*H. heidelbergensis*
Sel'ungur, Kyrgzstan	Late Middle Pleistocene	10 teeth, humeral fragment	Neanderthal/non-hominin?
Kara'in III.2, Turkey	ca. 200–250 ka	3 1st phalanges, 1 3rd phalange, left mandible fragment, cuboid, radius fragment	Neanderthal?
Kara'in, III.3	ca. 300–350 ka	Two vertebrae, femoral diaphysis	*Homo* sp. indet
Zuttiyeh, Israel	ca. 300 ka	Cranial	Various
Tabun E, Israel	ca. 400 ka	Molar, femoral fragment	*Homo* sp. indet.
Qesem, Israel	ca. 300 ka	8 teeth	*Homo* sp. indet
Koçabas¸ Turkey	Middle Pleistocene	Two cranial fragments	*H. erectus*
El Khowm, Syria	Middle Pleistocene	Cranial fragment	*H. erectus*

Sources: Dennell 2009, 2014; Glantz et al. (2008) (doubts over the Sel'ungir teeth); Kappelman et al. 2007 (Koçabas); Le Tensorer et al. 2006 (El Khowm); Hershkovitz et al. (2011) for Qesem

glaciation (see Table 1), many major issues of human evolution are difficult to resolve, particularly the relationships the inhabitants of West and Central Asia may have had with Europe, Africa, and the rest of Asia. For example, the earliest European fossil evidence for our genus is a mandible from Atapuerca, Spain, that is classified as *Homo* of indeterminate species, and dated to ca. 1.2 Ma (Carbonell et al. 2008); its source population in West Asia is unknown. According to Krause et al. (2010), the ancestors of the Denisovans – a population currently known only from analysis of the ancient DNA of a 30–48 ka human bone from Denisova Cave, Siberia – may have entered Southwest Asia from Africa ca. 1 Ma ago; an alternative view is that they originated in Asia (Martinón-Torres et al. 2010). Either way, there is no relevant skeletal evidence from West Asia. Around 800,000 years ago, Atapuerca was inhabited by *H. antecessor* (Carbonell et al. 1995). Both these populations were probably immigrants from West Asia and descendants of the Dmanisi hominins, but there is no equivalent to *H. antecessor* in West Asia. After 600 ka, the resident hominin in Europe was *H. heidelbergensis*, which some researchers believe also inhabited sub-Saharan Africa and perhaps even China. The only relevant finding from West Asia is a mandible from Azych Cave, Azerbaijan, that dates from the mid-Middle Pleistocene and was identified as *H. heidelbergensis*. In Europe, the descendants of *H. heidelbergensis* evolved into Neanderthals, and several examples are known from before the Upper Pleistocene (125–10 ka), but not for certain in West Asia (see Dennell 2009). The cranial specimen from Zuttiyeh Cave, Israel, is probably ca. 300 ka old, but there is no consensus over its identification (Sohn and Wolpoff 1993). Like, eight teeth from Qesem Cave, Israel, ca. 300-ks-old, are indeterminate. Although West Asia was likely a major corridor for hominins migrating into Europe and eastwards to South and East Asia between 1 Ma and 200 ka there is sadly almost no evidence of the hominin traffic that used it during this time.

Neanderthals and *H. sapiens*

The fossil hominin record of West Asia improves enormously for the last 150 ka. The evidence from the Levant is especially important for the large number of Neanderthal remains and also the earliest examples of *H. sapiens* outside Africa (see Table 2).

Early *Homo sapiens*

The earliest skeletal evidence for our species comes from Jebel Irhoud, Morocco (ca. 300 ka-old) and Ethiopia, ca. 190–160 ka. Recent evidence indicates that our species had already entered the Levant before the last interglacial (ca. 125–115 ka). An important recent discovery is that of a maxilla from Misliya Cave, Israel, that is dated to between 177,000 and 194,000 years old and is identified as that of *Homo sapiens.* It was found associated with Tabun-D type Middle Paleolithic assemblages (Hershkovitz et al. 2018). This discovery implies that our species may already have started to exit Africa before 170,000 years ago. Two other cave sites in Israel have produced unambiguous evidence of *H. sapiens* that is older than 70 ka (Shea 2003). The cave of Skuhl in Mount Carmel contained the remains of 16 individuals in levels B1 and B2 which have been dated by ESR and TL to between ca. 80 and 100 ka. The cave of Qafzeh has also produced evidence of 16 individuals, both on the terrace in front of the cave and from levels XVI to XXI inside. These are dated from between 80 and 120 ka by ESR and TL techniques. There is also some potentially important but ambiguous evidence from the cave of Tabun, Israel, which lies immediately adjacent to Skuhl, and has the most important and best-dated sequence of Middle Paleolithic stone tool assemblages in Southwest Asia. Two hominin finds are particularly important. The first (Tabun I) is a skeleton that was initially thought to have come from layer C, but more likely was an intrusive burial from layer B, dated by ESR to 122 ± 16 ka, and the second (Tabun II) is a mandible from layer C, which has been dated to 140 ± 21 ka (ESR) and 165 ± 16 (TL, on burnt flint). Both the mandible and skeleton have been identified as Neanderthal, but the mandible is unfortunately taxonomically ambiguous as some have identified it as *H. sapiens,* and others as Neanderthal. The Tabun II specimen is thus either an early Neanderthal or the earliest example of *H. sapiens* from outside Africa (or perhaps a hybrid, or a descendant of an indigenous, and currently undocumented, population). If the Tabun II mandible is regarded as that of a Neanderthal, it implies that Neanderthals were resident in the Levant before the last interglacial and also made the Mousterian assemblages before the appearance of *H. sapiens.* If on the other hand, the mandible is that of *H. sapiens*, it implies that it left Africa before the last interglacial and used Mousterian assemblages.

Neanderthals

If we exclude for the moment the Tabun II mandible, all Neanderthal finds from the Levant are younger than 70 ka (see Table 2). Many of these were deliberate burials. In level B of Amud Cave, Israel, a Neanderthal skeleton and other remains have been dated by TL and U-series to ca. 60–70 ka old, and at Kebara Cave, Israel, parts of a juvenile (Kebara I) were found in level F (later subdivided into units VI-XIII), and in later excavations, most of the postcranial skeleton of an adult male (Kebara II). These remains are dated to between 55 and 65 ka by ESR and TL. On current evidence, Neanderthals persisted in the Levant until 40–50 ka, when they are replaced, this time permanently, by *H. sapiens*.

Neanderthals are also widely distributed across west and Central Asia in the Upper Pleistocene in Marine Isotope Stages 3 and 4, ca. 70–40 ka. One of the best-known Neanderthal sites in West Asia is the cave of Shanidar, northern Iraq, where numerous remains were found from ca. 10 individuals in layer D. The youngest of these (Shanidar 1 and 5) lay above a charcoal sample that was radiocarbon dated to 46,990 ± 1500 and 50,600 ± −3000 BP. The oldest lie at depths beyond the range of radiocarbon carbon dating, and may date from shortly after, or even before, the last interglacial. The Shanidar finds include a partial skeleton, Shanidar 1, which exhibited multiple traumas even more severe than that routinely seen in many Neanderthal skeletons (Trinkaus and Zimmerman 1982). In Central Asia, the most important Neanderthal find is a child's skeleton from Teschik Tasch in Uzbekistan that was found in a late Mousterian context. For a long time, this was believed to be

the most easterly example of a Neanderthal, but recently some examples have been found in the Lake Baikal area of Siberia, 1500 km to the east, so Neanderthals had a very wide distribution during the last glaciation. Other evidence for Neanderthals in Central Asia has recently come to light. At Obi Rakhmat Grotto, Uzbekistan, six permanent maxillary teeth and 121 cranial fragments (all probably from the same 9–12-year-old individual) have been found in level 16 associated with a Middle Paleolithic assemblage; the age of the hominin remains is ca. 60–90 ka. At Anghilak Cave, also in Uzbekistan, a fragment of an adult fifth metatarsal (AH-1) was found in stratum IV, for which there are radiocarbon dates of 43,900 ± 2000 and 38,100 ± 2100 uncalibrated years BP (Glantz et al. 2008). There is also a recent find of a second deciduous incisor from the open-air site of Khudji, Tajikistan. This was found in horizon 8 in a late Middle Paleolithic context, dated by radiocarbon to ca. 40 ka uncalibrated years BP (Trinkaus et al. 2000). There is also a late Pleistocene upper third premolar (P^3) from Wezmeh, Iran, that has been identified as Neandertal (Zanolli et al. 2019) – the first positive indication of Neandertals in the Zagros Mountains. The only pertinent evidence from Afghanistan was a right temporal bone that was found in 1966 in a late Middle Paleolithic context at Darri-i-Kur, dated by radiocarbon to 30,000 BP., and identified as Neanderthal but this has been recently re-dated to only 4,500 BP (Douka et al. 2017) and is thus now irrelevant to discussions of human evolution in Central Asia. In the Caucasus, there are numerous caves with Middle Palaeolithic, Mousterian, assemblages, and Neanderthal remains have been found at the caves of Mezmaiskaya, Barakaevskaya, and Monasheskaya (Golovanova and Doronichev 2003). The first of these contained the remains of an infant Neanderthal from layer 3, dated at ≥36 ka. Analysis of the ancient DNA from one of its ribs showed that Neanderthals were genetically different from ourselves (Ovchinnikov et al. 2000).

A prevalent interpretation of this evidence is that Neanderthals greatly expanded their range eastwards and southwards in the last glaciation. Their appearance in the Levant after 70 ka has been attributed to worsening conditions at higher latitudes that forced them further south. As conditions improved, so they were able to expand eastwards to the Zagros Mountains and thence into Central Asia. We should bear in mind, however, the virtual absence of fossil evidence from Central Asia before 70 ka, so their apparent expansion eastwards may reflect our ignorance of what happened before this time.

Later *H. sapiens* in West and Central Asia

The earliest indication of post-Neandertal *H. sapiens* in West Asia is a partial cranium that was found in the cave of Manot, Israel, on a limestone ledge in a side chamber – unfortunately not associated with any archaeological material. As a result of sampling, 11 points of the calcite patina around the skull, an average uranium-thorium age of 54.7–65.5 ka was obtained. It is described as *H. sapiens* but with a mixture of modern and archaic features and may represent an immigrant population of *H. sapiens* that arrived in the Levant from Africa after ca. 60,000 years ago (Hershkovitz et al. 2015). Otherwise, there is disappointingly very little evidence for the earliest populations of *H. sapiens* that succeeded Neanderthals in West and Central Asia. The earliest skeletal evidence for our species in West Asia is the skull of an adolescent (a.k.a. "Egbert") and a maxilla (a.k.a. "Ethelruda") from the base of a long Aurignacian sequence at the cave site of Ksar Akil, Lebanon, dated to ca. 40–45 ka (Douka et al. 2013). Several isolated teeth attributed to *H. sapiens* were also recovered from the cave of Üçağızlı in Southwest Turkey and dated by ^{14}C as from 41.4 ± 1.1 to 29.1–0.4 uncalibrated ka BP (Güleç et al. 2007) but at least one is more Neandertal-like (Kuhn et al. 2009: 108). The changeover from Neanderthal to *H. sapiens* is likely to have been a complex process given the archaeological evidence for the replacement of Middle Paleolithic, Mousterian assemblages to Upper Paleolithic ones between 45 and 30 ka.

Future Directions

There are several obvious directions in which future research into human evolution in West and Central Asia could proceed. The most obvious need is to increase greatly the number of hominin specimens (particularly cranial and mandibular ones) for Central Asia before 30 ka, and for West Asia between 1.75 Ma (the age of the Dmanisi specimens) and 150 ka (the age of the Tabun II mandible). At present, the fossil record for *Homo* in West and Central Asia is relevant to two separate themes: the earliest appearance of our genus ca. 1.85 Ma ago outside Africa (as evidenced by the Dmanisi finds), and the earliest examples of *H. sapiens* outside Africa and their Neanderthal contemporaries in the last 200,000 years. These themes need to be linked to provide a record of what happened between these two events.

Five gaps are especially important to fill in West Asia: (i) the identification of the source population that first colonized Europe (on current evidence) ca. 1.3–1.4 Ma; (ii) the identification of the source population of *H. antecessor*, ca. 1 Ma–800 ka; (iii) the identification of the African immigrants that introduced African types of cleavers and handaxes to the Levant ca. 800 ka (as evidenced at Gesher Benot Ya'aqov); (iv) the identification of the source population of *H. heidelbergensis* that entered Europe after 600 ka; (v) to determine whether Neanderthals in West Asia developed indigenously, or were immigrants; and (vi) to determine more precisely than at present when *H. sapiens* first entered the Levant.

Another direction for future research is to establish the climatic context of hominin settlement. At present, very little of the archaeological and fossil hominin record of West Asia can be confidently linked to a specific type of climate. A useful beginning would be to establish whether hominins were present in warm, moist (interglacial) periods, or cool, drier periods (=glaciations). One of the best examples in Asia of this type of linkage is from Tajikistan, where Paleolithic sites are consistently found in interglacial paleosols and not in glacial loess deposits (Ranov 1995): hominins were thus present in Tajikistan in warm periods, but not cold ones. As mentioned above, aridity was one of the key variables affecting Pleistocene human settlement in West and Central Asia, and the core, or long-term resident, populations were likely restricted to areas with dependable, year-round water, as these were the ones most likely to persist throughout cold, dry periods as well as moist, warm ones. Until we can establish the climatic context of hominin settlement, it is not possible to investigate how hominins responded to climatic and environmental changes, expanded or contracted their distribution, or colonized neighboring regions.

Future directions need also to include conceptual developments. One particularly relevant to investigations of Neanderthals and early *H. sapiens* in Asia is to move away from a rigid, dichotomized framework in which the Neanderthals and *H. sapiens* are mutually exclusive terms. One major justification for doing so is that one might expect a variable fossil record in areas such as the Levant if populations repeatedly, under the changing conditions of the Pleistocene, expanded and contracted their distribution, overlapped and interacted with others, fused with others, or fragmented. Another justification is the recent evidence that Neanderthals and early *H. sapiens* interbred, with the result that all Eurasians contain some Neanderthal genes (Green et al. 2010). There is also, particularly in Central Asia, the currently unseen presence of the Denisovans (see above). If they were a sister species of Neanderthals, they will also need to be accommodated in assessments of fossil hominin specimens. Assuming that the Denisovans will be confirmed as a genetic reality, we may find that a simple binary choice between Neanderthals and *H. sapiens* is insufficient for correctly identifying Upper Pleistocene specimens and populations.

Finally, the expansion of *H. sapiens* into West and Central Asia needs to be envisaged as a process that involved several dispersal events, some of which may have been short-term and thus failures. The early presence of *H. sapiens* in the Levant before 170 ka may be an example of a failed dispersal event (Shea 2008), and its

eventual expansion into Central Asia may well have involved several dispersal events, as well as occasional contractions and extinctions. Likewise, Neanderthal population demography is also likely to have been complex under the highly variable conditions of MIS 6–3, 160–40 ka.

West Asia: Paleolithic

Seiji Kadowaki
Nagoya University Museum, Nagoya University, Nagoya, Aichi, Japan

Introduction

West Asia is a key locale for the investigation of Paleolithic human migration and adaptation because of the area's location at the crossroads between Africa and Eurasia as well as its diverse environmental settings. Geographic units in west

Asia comprise the Levant, the Zagros and Taurus Mountains, Anatolia, the Caucasus, and the Arabian Peninsula. In the Levant, east Mediterranean coastal plains and the rift valley extending between the Red Sea and the Afrin Basin provided significant habitats and migration routes for early humans during the Paleolithic. To its east, inland areas of the Syrian Desert and the Jordanian Badia are presently under arid environments, but the inland basins, often associated with oases, such as el-Kowm, Palmyra, Azraq, and Jafr, used to hold Pleistocene lakes, around which prehistoric sites are clustered. The rugged terrains and cave systems in the Zagros–Taurus and the Caucasus Mountains have also been important fields for the study of early human habitations. In the Arabian Peninsula, a number of Paleolithic sites have been located in various environmental settings, including coastal plains, foothills of the Asir and Hadhramaut Mountains, as well as near wadis and lakeshores in interior plains.

Geographic connections between west Asia and surrounding regions are structured by water mass and mountain ridges (Fig. 1). One of the routes to Africa is through the northern Sinai between the Southern Levant and the Upper Nile area. Another is Bab el-Mandab between the Lower Awash River and the southwestern corner of the Arabian Peninsula. Land routes to northern areas are bounded by the Mediterranean Sea, Black Sea, and Caspian Sea, and the one between the latter two is truncated by the Caucasus Mountains. The landmass to South and Central Asia is the Iranian plateau flanked by rugged terrains of the southern Zagros Mountains along the Persian Gulf and the Alburz Mountains at the southern Caspian shore.

Definition

Early, Middle, and Late Pleistocene

In 2009, the International Union of Geological Sciences lowered the base of the Pleistocene epoch to include the Gelasian Stage that began c. 2.6 Ma. Thus, the former "Late Pliocene" corresponds to the current "Early Pleistocene." However, the stages for the Middle and Upper Pleistocene are unchanged with their beginnings at the Brunhes–Matuyama reversal and the last interglacial, respectively.

Hominin

The term "hominin" is used to denote human ancestors instead of the old term "hominid," which is currently used to mean ancestors of humans, chimpanzees, gorillas, and orangutans.

Historical Background

Investigations of some key Paleolithic sites in west Asia were initiated in the 1920s and 1930s, as exemplified by the excavations by Dorothy A.E. Garrod at Mt. Carmel and Southern Kurdistan, René Neuville at the Judean Desert, and Turville-Petre at the Galilee area and Kebara Cave. These early systematic excavations provided fundamental archaeological records for the definition of Paleolithic cultures and their chronological sequences. Initial influence from European prehistory on cultural names (e.g., Aurignacian, Levalloiso–Mousterian, and Tayacian) was subsequently modified into or replaced with locally defined cultural entities (e.g., Levantine Aurignacian, Ahmarian, Levantine Mousterian, and Yabrudian). While early investigators tended to focus on deep cultural deposits at caves in an effort to establish Paleolithic cultural sequences, subsequent surveys, and excavations of open-air sites in the inland areas, such as Negev, Sinai, Badia, and Syrian Desert, led to the recognition of greater diversity of Paleolithic entities as well as dynamic adaptation of prehistoric populations to various environments.

The progress and intensity of Paleolithic research in west Asia varies depending on geographic areas. The Levant has been most intensively studied since the 1920s, providing fundamental data sets for studying Paleolithic populations in west Asia. Although the Zagros region received early investigations from the

West Asia: Paleolithic, Fig. 1 Map of west Asia showing sites mentioned in the text. The following site names are in alphabetical order and associated numbers correspond to those in the map: Abu Hureyra (63), Abu Noshra (70), Abu Sif (34), Ain al-Buhayra (48), Ain Difla (47), Ain Mallaha (10), Ain Qasiyya (36), Ain Rahub (18), Amud (15), Antelias (6), Azariq (42), Azraq (36), Azykh (56), Beidha (49), Berekhat Ram (9), Bezez (8), Bisitun (75), Boker (44), Boker Tachtit (44), C-Spring (36), Dawādmi (83), Dederiyeh (60), Dhofar (82), Dmanisi (55), Douara (66), Dursunlu (58), Ein Aqev (44), Ein Gev (16), el-Kowm (64), el-Wad (24), Emireh (15), Erq el-Ahmar (33), Eshkaft-e Gavi (79), Evron (11), Far'ah II (40), FAY-NE 1 (81), Fazael (31), Gar Arjeneh (78), Gesher Benot Ya'aqov (13), Gharmachi 1b (65), Hatoula (29), Hayonim (12), Holon (27), Humian (77), Hummal (64), Jayroud (5), Jerf Ajla (66), Jilat (39), Karain (59), Kebara (25), Keoue (1), Khallat Azana (35), Kharaheh IV (38), Ksar Akil (6), Kudaro I (53), Kunji (78), Lagama (67), Latamne (65), Lion Spring (36), Mar Gurgalan Sarab (76), Mureybet (62), Mushabi (68), Naamé (7), Nachcharini (3), Nadaouiyeh (64), Nahal Aqev (44), Nahal Ein Gev I (16), Nahal Oren (23), Nizzana (43), Ohalo II (17), Öküzini (59), Ortvala Klde (54), Palegawra (73), Pa Sangar (78), Qafzeh (21), Qesem (26), Quneitra (14), Ramat Matred (45), Raqefet (22), Ras el-Kelb (6), Rasfa (20), Revadim (30), Rosh Ein Mor (44), Rosh Horesha (46), Rosh Zin (44), Saaide (2), Saflulim (46), Salibiyah (32), Shanidar (71), Shekaft-i Ghad-i Barm-i Shur (80), Shukba (28), Shunera (41), Skhul (24), Tabaqa (48), Tabun (24), Tor Faraj (52), Tor Fawaz (52), Tor Hamar (69), Tor Sabiha (51), Tor Sadaf (48), Tor Sageer (48), 'Ubeidiya (17), Üçağizli (61), Umm el-Tlel (64), Umm Qatafa (33), Uwaynid (37), 'Uyun al-Hammam (19), Wadi Aghar (52), Wadi Fatimah (84), Wadi Hammeh (19), Wadi Judayid (51), Wadi Mataha (50), Warwasi (74), Yabrud (4), Yafteh (78), Yarimburgaz (57), Yutil al-Hasa (48), Zarzi (72), Zuttiyeh (15)

1920s to 1950s, subsequent fieldwork has been prevented by geopolitical instability. Renewed investigations of Paleolithic sites have recently increased in Anatolia, the Caucasus, southern Iran, and the Arabian Peninsula in relation to the study of early *Homo* species and *Homo sapiens* dispersals out of Africa.

Key Issues/Current Debates

Lower Paleolithic

Earliest Hominin Occupation in West Asia

Currently, the earliest evidence for human occupation in west Asia is known at Dmanisi,

Georgia, in the southern Caucasus (e.g., Gabunia et al. 2001). Archaeological deposits at Dmanisi overlie the Masavera basalt that was dated to c. 1.8–2.0 Ma by $^{40}K/^{40}Ar$ and $^{40}Ar/^{39}Ar$ dating. This basalt and the lower archaeological layers (units A1 and A2) show normal polarity directions (the Olduvai Subchron), while the upper ones (units B1 and B2) have a reversed polarity (the Matuyama Chron). Well-preserved bone remains include four hominin crania, three mandibles, and a number of postcranial specimens. These hominin remains have been identified as the primitive form of *Homo erectus/ergaster* or placed in a new taxon named *Homo georgicus*. Rich faunal remains at Dmanisi include Early Pleistocene types mostly of Eurasian species and indicate grassland with some forest as the local environment. Chipped stone artifacts from the site primarily consist of unmodified flakes and chopping tools, and this lithic industry is called "Pre-Oldowan." These observations let researchers to consider that the first colonization of west Asia took place at the early stage in the evolution of genus *Homo* before the appearance of the handaxe technology or the Acheulian tradition. Some researchers also propose the possibility that *Homo erectus* originated in Asia and that some of them migrated into Africa.

Acheulian Tradition

Much of the Lower Paleolithic records in west Asia comprise Acheulian assemblages with a varying amount of bifaces, i.e., hand axes and cleavers (Fig. 2). A large number of Acheulian finds are reported in west Asia, and their accounts accumulated in the last decade particularly in Anatolia, the Caucasus (e.g., Azykh and Kudaro I), and the Arabian Peninsula (e.g., Wadi Fatimah and Dawādmi) in addition to the Levant. However, the number of sites with clear contexts and dates is limited. The dates are estimated by several different methods, including radiometric dating, paleomagnetic analysis, paleontological comparison, and the paleoenvironmental examination of marine and fluvial deposits. Researchers proposed several chrono-cultural entities within the Acheulian tradition, such as Early, Middle, Late, Late evolved, and Final Acheulian on the basis of techno-typological attributes of bifaces (Bar-Yosef 1994).

The earliest assemblages with bifaces in west Asia are currently known from the Early Pleistocene lake deposits at 'Ubeidiya, Israel, located 3 km south to the Sea of Galilee. The site has numerous publications on the geological and sedimentological studies as well as lithic and faunal analyses. The comparison of fauna with those dated in the African and European sequences

West Asia: Paleolithic, Fig. 2 Hand axes from the middle Euphrates region

provided a date estimate (c. 1.4 Ma) of the site. Only a small portion of animal bones show cut marks, and recent sedimentological and faunal analyses suggest that archaeological remains at ‘Ubeidiya were deposited as a result of low energy fluvial processes rather than “living floors” at the lakeshore. The industry of chipped stone artifacts from ‘Ubeidiya has been identified as Early Acheulian or Developed Oldowan, characterized by core choppers, polyhedrons, spheroids, and crude bifaces that occur in varying frequencies in different layers. These tool types tend to differ from each other in the selection of raw materials: bifaces are often made from basalt, chopping tools, and polyhedrons from flint, and most spheroids from limestone.

The water-logged site of Gesher Benot Ya‘aqov (GBY), also located in the Jordan Valley, is dated to c. 0.7–0.8 Ma by paleomagnetic analyses, which show that lacustrine deposits with archaeological remains deposited over the Brunhes–Matuyama boundary. Lithic industry of GBY, designated as Acheulian, is characterized by the preferential use of basalt for bifaces, i.e., hand axes and cleavers, the blanks of which are frequently provided by the Kombewa technique. These technological features have been interpreted as evidence for a hominin dispersal from Africa. Both African and Levantine taxa constitute micromammalian remains. Notable is the recovery of an elephant skull from an archaeological horizon at level 1 in layer II-6. Whether this skull resulted from hunting, scavenging, or natural mechanisms has been investigated through a series of taphonomic studies. Well-preserved plant remains include fruit, seeds, bark, and wood, and the excavators suggest that numerous pitted stones from the site were used for cracking nuts. In addition, the use of fire at GBY has been suggested through taphonomic examination of burnt remains (Alperson-Afil and Goren-Inbar 2010).

The accounts of Latamne in the Orontes Valley and Joub Jannine II in the Beqqa Valleys often classify their lithic assemblages as Middle Acheulian or estimate their age to the Middle Pleistocene. In contrast to these Middle Acheulian sites that are clustered in the Mediterranean environmental zones, the Late Acheulian or late Lower Paleolithic sites are more widely distributed both in the Mediterranean areas (e.g., Holon, Tabun, Umm Qatafa, and Garmachi 1b) and at inland areas (e.g., Lion Spring, C-Spring, and the sites in the el-Kowm basin), suggesting the adaptation to drier settings or climatic amelioration during the Late Acheulian period.

The date of Berekhat Ram in the northern Golan Heights is broadly estimated as c. 230–780 ka, and its lithic assemblage is characterized by the high proportion of Levallois products and Upper Paleolithic tool types, i.e., end scrapers and burins, with few bifaces. The site is well known for the stone “figurine,” which has been accepted as an artificially modified object after rigorous examination by microscopes and experimental production.

Hominin fossils associated with Acheulian artifacts are very limited. A right lower incisor from ‘Ubeidiya has been broadly assigned to the genus *Homo*. At the site of Nadaouiyeh Aïn Askar in the el-Kowm basin, a fragment of left parietal bone was found in an Acheulian level that is characterized by oval hand axes and estimated as 450 ka. The bone was classed as *Homo erectus*.

Technological Variability: Flake Assemblages and the Yabrudian Complex

Some Lower Paleolithic assemblages lack bifaces. Such examples include the sites of Evron Quarry, Bizat Ruhama, Tabun layer G, Hummal level 13–14, and some sites in the Orontes and Euphrates Valleys. These occurrences have been explained in several different ways. The first one regards them as representing separate cultural entities, naming them the Tayacian or the Khattabian. Another position is to see them as a response to limited availability of raw materials. In addition, insufficient sample size has been pointed out as a reason for the absence of bifaces at some sites.

A more numerously documented example of the Lower Paleolithic technological variability is the Yabrudian complex (also called the Acheulo-Yabrudian or the Mugharan) (Ronen and Weinstein-Evron 2000). The complex comprises flake-based industries with heavily retouched

scrapers and a varying amount of bifaces (i.e., the Yabrudian and the Acheulo-Yabrudian) and blade-based industries with higher proportions of Upper Paleolithic tool types (i.e., the Amudian and the Pre-Aurignacian). The distribution of this complex is currently known in the central and northern Levant. The southern end is at Qesem Cave, the northern limit is at Dederiyeh Cave (Fig. 3), and the easternmost site is in the el-Kowm basin. This complex always occurs stratigraphically above the Late Acheulian and below the Tabun D type of the Levantine Mousterian tradition as seen at Tabun, Yabrud I, el-Kowm, and Dederiyeh. Along with this stratigraphic evidence, radiometric dates obtained from Qesem, Yabrud I, and Tabun layer E suggest the age of the Yabrudian between 200 and 400 ka at the end of the Lower Paleolithic. The Acheulian tradition, however, may have continued during this period in the Southern Levant, where the Yabrudian complex is not distributed. Zuttiyeh Cave has yielded hominin fossil associated with

West Asia: Paleolithic, Fig. 3 Yabrudian stone artifacts from Dederiyeh Cave (layer F in K22 and K23). (After Nishiaki et al. 2011a)

this complex. The skull from this cave has been placed in several different taxons, including archaic *Homo sapiens*. More recently, human teeth from Qesem Cave have been suggested to represent a new, locally developed, post *Homo erectus* lineage.

In Anatolia, the cave of Karain E yielded flake-based assemblages in the first two phases of the archaeological sequence (called Clactonian and Charentian), followed by the Mousterian in phase 3. Another flake-dominated assemblage without bifaces or the Levallois technique has been documented from Yarimburgaz Cave, whose estimated age is mid-Middle Pleistocene on the basis of the faunal remains. The apparent contemporaneity of these industries with the Yabrudian complex in the Levant may have implications for some of their common technological aspects.

Middle Paleolithic Period

Cultural Variations and Their Chronology

The account of the Middle Paleolithic cultural variability usually refers to three lithic industries, the Tabun B-, C-, and D-types (or phases 1, 2, and 3: Shea 2003), which have been defined by the techno-typological attributes of lithic assemblages from layers B, C, and D of Tabun Cave. The three industries are grouped under the Levantine Mousterian tradition (Fig. 4), and their common use of the Levallois technique distinguishes themselves from the preceding Yabrudian complex. The Tabun D-type is characterized by the production of blades and elongated points both with the Levallois method and the "laminar system." A significant number of Upper Paleolithic tool types occur in the D-type assemblages. In contrast, unilateral sidescrapers are representative

West Asia: Paleolithic, Fig. 4 Mousterian stone artifacts from Dederiyeh Cave (layer E in K22). (After Nishiaki et al. 2011a)

in the Tabun C-type industry, which often produces oval flakes with some points and blades from centripetally and/or bidirectionally prepared Levallois cores. The Levallois cores of the Tabun B-type are frequently prepared by unidirectional convergent flaking that produces broad-based points with some blades. Sidescrapers are dominant in retouched tools with few Upper Paleolithic types. The attribution of some lithic assemblages to these industries is shown in Table 1.

Besides Tabun Cave, the stratigraphic sequence of the Tabun B-, C-, and D-type industries is observable at only a few sites, such as Hayonim Cave (the D-type in layers F and lower E followed by the C-type in upper layer E), and probably Douara Cave (the D-type in unit IV followed by the C-type in unit III). As such, the current scheme of the Levantine Mousterian chronology primarily draws upon radiometric dating methods, e.g., TL, ESR, U-series, and amino acid racemization, which have been applied to the sites including Tabun, Hayonim, 'Ain Difla, Rosh Ein Mor, Qafzeh, Skhul, Naamé, Kebara, Amud, Tor Faraj, Tor Sabiha, Quneitra, Ksar Akil, and Far'ah II. These radiometric dates overall indicate that the three industries occurred in a general order from the Tabun D- through C- to B-type between 250 and 47 ka.

There are several dating results that could suggest the temporal overlap between different industries. For example, the dates proposed for 'Ain Difla (c. 100 ka) and Nahal Aqev (c. 70–90 ka) indicate that the Tabun D-type industry lasted longer in the southern arid areas, while it was replaced by the Tabun C-type in the north. In addition, revised ESR dates (c. 100–120 ka) for Tabun layer B is closer to the dates of the Tabun C-type assemblages at Qafzeh and Skhul than those of Tabun B sites, such as Kebara and Amud. However, these anomalous dating results remain to be verified by additional samples with more secure contexts.

The faunal sequence has also contributed to the establishment of the Middle Paleolithic chronology. For example, faunal assemblages, particularly micromammals, from layers XV to XXV of Qafzeh, associated with the Tabun C-type assemblages, are characterized by the increase of Afro-Arabian elements adapted to savanna conditions. This is interpreted to represent the northward expansion of Afro-Arabian species with anatomically modern humans during MIS 5. In contrast, almost all the Afro-Arabian elements are eliminated in the faunal assemblages at Tabun B sites, such as Kebara and Amud, where Palearctic–European elements are dominant as a result of their southward dispersal with Neanderthals during the cold and dry climate of MIS 4. The faunal assemblages of both Hayonim lower and upper E, associated with Tabun D-type and C-type industries, respectively, are characterized by the presence of earlier Pleistocene elements and the dominance of Palearctic mammals, indicating their chronological precedence to Qafzeh. These accounts for bio-cultural chronology generally fit the radiometric dates of Qafzeh, Kebara, Amud, and Hayonim E, although the suggested correlation of the fauna from Tabun layer B to MIS 4 does not fit the ESR dates mentioned above.

Middle Paleolithic assemblages are profuse also in other areas in west Asia. Those in the Zagros–Taurus regions are classed as the Zagros Mousterian, which is characterized by the frequent application of retouch that produces various forms of scrapers. Recent studies suggest that core reduction technology involves Levallois methods that tend to produce elongated blanks by linear flaking directions. Similar technological characteristic is noted at Ortvala Klde in the southern Caucasus. Revised TL dates for the earliest Mousterian assemblage (F) at Karain E are c. 200–250 kya, indicating that the Mousterian tradition in this region started before the last interglacial like the Levantine Mousterian. In addition, recent finds in southern Iran and southern Arabia report the association of bifacial foliates or Nubian Levallois products, indicating greater variability of Middle Paleolithic assemblages in west Asia.

The Timing of Neanderthal and Modern Human Occurrences

The Neanderthal occupation in west Asia is attested by the fossil evidence from Kebara, Amud, Tabun, Dederiyeh, Shukhba, Shanidar, and Bisitun Caves. The contexts of Neanderthal fossils are mostly dated to the late Middle

[e]Either identification of hominin types or association with lithic industries is unclear

Paleolithic between 47 and 75 ka during MIS 4 on the basis of radiometric dates, stratigraphic positions, faunal spectra, and/or lithic-technological attributes. In contrast, early modern humans recovered in the Middle Paleolithic strata of Qafzeh and Skhul have been given earlier dates (c. 75–130 ka) corresponding to MIS 5 by a series of radiometric dates and the analyses of faunal assemblages.

There are some fossil records that indicate the earlier occurrence of Neanderthals in west Asia, but these cases need further supporting data to be accepted. For example, layer III.2 of Karain E, associated with human remains with some Neanderthal traits, has been dated around 200–250 kya by TL. Another case is the Tabun C1 skeleton, which is broadly recognized as representing Neanderthal features, but some researchers, including excavators, consider that the specimen may have infiltrated down from layer B on the basis of the field observation as well as the more recent analysis of U/Th ratios. Although this makes the fossil stratigraphically later, the revised ESR date for Tabun layer B (c. 100–120 ka) is significantly older than the dates of other sites with Neanderthal fossils, such as Amud and Kebara, and closer to those of Qafzeh and Skhul with early modern humans. In addition, the stratigraphic affinity of the Tabun C2 specimen to layer C is unequivocal, but its biological affinity has been controversial, representing both Neanderthal and modern human attributes. If the Neanderthal affinity is accepted, the TL and ESR dates of Tabun layer C (120–180 ka) suggest that Neanderthals appeared in the Levant before modern humans at Qafzeh and Skhul. In contrast to these possibilities of the early appearance of Neanderthals, there is currently no evidence for the existence of *Homo sapience* during the age between 47 and 75 ka in west Asia.

Hunting, Residential, and Symbolic Behavior

Faunal remains deposited as human refuse in the Middle Paleolithic include various ungulates (e.g., gazelle, fallow deer, red deer, roe deer, aurochs, and onager) and large reptiles that are easy to capture (e.g., tortoise and legless lizards). The seasonality of site use and mobility appears to have been variable. For example, the analyses of cementum increment of gazelle teeth suggest multi-seasonal occupation of the sites with Neanderthal fossils, such as Tabun layer B and Kebara, in contrast to shorter-term occupation at sites associated with *Homo sapiens* fossils, such as Tabun layer C and Qafzeh XVI–XXIII (Lieberman 1993). The relatively high residential stability at Kebara, indicated by dense accumulation of refuse and the prolonged use and maintenance of hearths, contrasts to the ephemeral occupation at Hayonim layer E (Meignen et al. 2006). At the rockshelter of Tor Faraj, associated with the Tabun B-type assemblage, the structured use of living space has been documented through the examination of the arrangement of hearths and the distribution of artifacts and phytoliths (Henry 2004). The evidence for symbolic objects is limited, but the use of ochre in burials and ochre-stained ground stones at Qafzeh is well known (Hovers et al. 2003). In addition, perforated sea shells from Qafzeh and Skhul may have been used as beads.

Upper Paleolithic Period

Origin: Initial Upper Paleolithic

The beginning of the Upper Paleolithic period is marked by the Initial Upper Paleolithic (IUP or Emiran) industry that is technologically characterized by the introduction of prismatic cores and the production of pointed blades with relatively large, sometimes facetted, striking platforms. The IUP is also typologically defined by the high occurrences of Upper Paleolithic tools, i.e., burins and end scrapers, with some fossil indices, such as Emireh points and chamfered pieces. A series of ^{14}C and TL dates from IUP sites range between 47 and 33 ka, within which Boker Tachtit is dated older than northern IUP sites at Üçağızlı Mughara, Umm el-Tlel, and Jerf Ajla. Despite the recent accumulation of IUP assemblages, the debate over their origin continues (Bar-Yosef and Belfer-Cohen 2010) with a view of this industry as representing a transitional phase from the Middle to Upper Paleolithic period and the other position maintaining that the IUP culture was brought by *Homo sapiens* dispersing from Africa.

West Asia: Paleolithic, Fig. 5 Upper Paleolithic chipped stones from the middle Euphrates region

Upper Paleolithic Cultural Variations

Accounts for the techno-typological variability of Upper Paleolithic chipped stones after the IUP often refer to two cultural traditions, i.e., the Ahmarian (Fig. 5) and the Levantine Aurignacian. The former appeared earlier at c. 43/38 ka, following the IUP, and it features dominant production of blades/bladelets that are modified into pointed or backed forms. In contrast, the beginning of the Levantine Aurignacian is dated to at least a few millennia later around 35 ka, and it is characterized by numerous flakes created into burins and scrapers, and high occurrences of twisted bladelets detached from carinated tools/cores.

The variations within the Levantine Aurignacian tradition have been traditionally grouped into phases A, B, and C on the basis of stratified assemblages from Ksar Akil layers VI–XIII. Among the three phases, part of the Levantine Aurignacian B and C (i.e., layers VII and VIII) shows "classic" Aurignacian elements, such as flat frontally carinated and nosed scrapers along with bone and antler artifacts, such as split-based points, similar to the European Aurignacian. The origins of the Levantine Aurignacian tradition are usually assumed outside the Levant, such as southeastern Europe and the Zagros region (Olszewski and Dibble 2006). Relevance of flake-based assemblages mainly distributed in the arid marginal zone to the Aurignacian tradition has been debated, and they have recently been classed as a separate industry called the Arqov/Divshon (Goring-Morris and Belfer-Cohen 2006).

The Ahmarian tradition is often subdivided into the early and late phases. The Late Ahmarian is characterized by the increase of Ouchtata bladelets replacing el-Wad points, as well as the employment of multiple core-reduction strategies for bladelet production. In addition, some of the Late Ahmarian assemblages, such as Ohallo II, include microlith types that are hallmarks of the Kebaran, one of the early Epipaleolithic entities. As such, the Late Ahmarian has been renamed by some scholars as Masraqan (Goring-Morris 1995). In either way, Late Ahmarian/Masraqan lithic assemblages are likely to represent a transitional phase from the Upper to Epipaleolithic period. Their continuous transition is also indicated by the overlapping range of ^{14}C dates between the Late Ahmarian and the Early Epipaleolithic, particularly the Nebekian sites in Wadi el-Hasa.

Settlement, Subsistence, and Symbolic Behaviors

The extensive distributions of Upper Paleolithic settlements, particularly those of the Ahmarian and the Arqov/Divshon, in the steppe/arid zone have been documented in the Negev, northern Sinai, and southern Jordan. In contrast, the sites

of the "classic" Levantine Aurignacian and the Atlitian tend to occur in the Levantine core areas. In both regions, the sites are small with relatively thin deposits containing several hearths at most, indicating their ephemeral nature and the high residential mobility, which are consistent with the circular settlement pattern proposed for the Upper Paleolithic inhabitants in the central Negev. A similar view on Upper Paleolithic occupation has been presented by the seasonality study of gazelle hunting (Lieberman 1993) and the decreasing trend in the proportions of commensal species (e.g., house mice) from the Middle to Upper Paleolithic layers at Qafzeh, Sefnim, and Kebara caves.

Large mammal bones from Upper Paleolithic sites mostly consist of ungulates including gazelle, fallow deer, red deer, aurochs, wild goat, boar, and equid with greater focus on smaller species (i.e., gazelle) than that of the Middle Paleolithic. In addition, intentional exploitation of small prey (e.g., hares, birds, and small turtles) is suggested at sites like Ksar Akil, Hayonim, Kebara, and Ohalo II. At the latter site, evidence for fishing is also present. Although botanical remains from Upper Paleolithic sites are scarce in west Asia, they are exceptionally well preserved at a waterlogged, Late Ahmarian/Masraqan site of Ohalo II at the lakeshore of Galilee. The record suggests the exploitation of a wide range of grass species, including wild barley and emmer wheat, which were probably processed on ground stones, as suggested starch grain analysis (Piperno et al. 2004).

Art objects rarely occur in the west Asian Upper Paleolithic, but animal teeth pendants and incised limestone slabs from Hayonim Cave offer common features between the Levantine and European Aurignacian. In addition, numerous sites of both the Ahmarian and Levantine Aurignacian traditions yielded ochre fragments, ochre-stained stones, or marine shells, the latter of which are sometimes perforated, as reported at Üçağızlı and Yabrud II. Rare human burials have been discovered at Nahal Ein Gev I and Ohallo II, while isolated human bones have been recovered from Ksar Akil, Antelias, Qafzeh, Kebara, and el-Wad. The paucity of burials may be related to the ephemeral nature of Upper Paleolithic settlements.

Epipaleolithic Period

Cultural Chronology

Like preceding Paleolithic periods, Epipaleolithic material cultures are primarily defined by lithic evidence but classed into much greater numbers of categories. This is mainly related to the variability in the morphology and production technique of Epipaleolithic microliths, on which researchers draw to define cultural entities (Goring-Morris 1995; Olszewski 2008). In the Levant, Epipaleolithic cultures are often grouped into the early, middle, and late phases (Table 1). In general, non-geometric forms of microliths are dominant in the early phase, while geometric microliths mark the middle (e.g., trapeze/rectangle and triangle) and late phase (e.g., lunate) (Fig. 6). Furthermore, the presence/absence of microburin technique, a specific method for segmenting bladelets, shows temporal and geographic patterns, providing a criterion to distinguish between the Kebaran (absent) and the Nebekian (present) in the early phase, and between the Geometric Kebaran (absent) and the Mushabian (present) in the middle phase. The microburin technique is more widespread in the Late Epipaleolithic, or the Natufian cultural complex, which is divided into the early, late, and sometimes final phases. Recent recovery of some Early Natufian sites in steppe areas in Jordan indicate that a range of environment inhabited by Early Natufian foragers was wider than previously envisioned.

Microlithic assemblages in the Zagros region are classified as the Zarzian, although their chronological data are limited. Numerous Epipaleolithic cave sites have also been discovered in the Antalya area, Turkey, including Öküzini Cave, where stratified assemblages show a diachronic trend from non-geometric to geometric microliths as in the Levant and the Zarzian. Another microlithic industry with geometric microliths, the Trialetian, has been proposed for the assemblages in the Caucasus, eastern Anatolia, and the Iranian plateau.

West Asia: Paleolithic, Fig. 6 Late Epipaleolithic chipped stones from Dederiyeh Cave. (After Nishiaki et al. 2011b)

While some researchers suggest that morphological variability of microliths can be caused by their re-modification for prolonged use rather than by intentional stylistic differences, others consider that both functional and stylistic variability recognized for distinguishing between different entities is likely to represent social groups with different technological traditions, adaptive strategies and/or territories. In the case of the Natufian complex, its regional and temporal variability is also manifested in groundstone artifacts, architecture, ornamental objects, decoration motifs, and burials.

Mobility Pattern, Subsistence, and Society

Early and Middle Epipaleolithic sites are generally small and have thin occupational deposits, indicating that inhabitants have continued high residential mobility since the Upper Paleolithic period. The seasonality analysis of gazelle hunting also suggests that Kebaran and Geometric Kebaran occupations were seasonal in contrast to multi-seasonal occupations during the Natufian and Mousterian periods (Lieberman 1993). However, a few Early and Middle Epipaleolithic sites are quite large, even allowing for the effect of deflation and sheetwash (e.g., Jilat 6), associated

with hut structures (e.g., Ein Gev III, Kharaneh IV, and Umm el-Tlel), and/or human burials (e.g., Neve David, Kharaneh IV, and 'Uyun al-Hammam). These sites point to a long-term change rather than a sudden shift in settlement system towards the Natufian culture. The increased sedentism of Natufian foragers is illustrated by many lines of evidence, including stone-walled structures, storage facilities, numerous human burials, large site size, dense archaeological remains, and the increase in human commensals, such as house mice (Valla 1995). Multi-seasonal occupation is also indicated by seasonally available faunal and botanical species and the analysis of cementum increment of gazelle teeth.

Game species during the Epipaleolithic period include gazelle, equids, aurochs, cervids, caprines, hare, tortoise, and birds. While similar range of species was exploited in the Natufian, gazelle hunting was more intensified. Direct evidence for plant diet during the Epipaleolithic is rare, but botanical remains from a few Natufian sites, such as Abu Hureyra, Dederiyeh Cave, Wadi Hammeh 27, and Hayonim Cave, attest the use of wild cereals (e.g., barley, einkorn, and rye), wild legumes (e.g., lentils and vetches), wild nuts (e.g., almonds and pistachios), and wild fruits. Intensive exploitation of cereals during the Natufian is also suggested by indirect evidence, such as glossed blades and numerous food processing tools, particularly mortars and pestles.

Long-distance distribution of marine shells continued, and possibly was enhanced, from the Upper to Epipaleolithic period. Their occurrences at inland sites and patterned associations with particular lithic industries are interpreted as representing social interactions through the exchange of shells that are often pierced (Ritcher et al. 2011). Some Early Natufian sites (e.g., el-Wad) yielded numerous shell/bone beads as grave goods, such as a necklaces and a headdress, but their social significance remains controversial. The increase of human burials also distinguishes the Epipaleolithic from the Upper Paleolithic culture. In early Natufian villages, burials are often placed in and near residential space.

In sum, the generally increasing trend in sedentism and cereal use, as well as the development of burial customs and exchange of exotic materials during the Epipaleolithic, is widely considered precursors of sedentary villages, food production, and social practices in the following Neolithic period, although the transitional process was complex and variable at different parts in west Asia.

International Perspectives

Although Paleolithic research in southern Arabia and southern Iran has been underdeveloped in comparison to those in the Levant, recent fieldwork in the former areas discovered Middle Paleolithic stone assemblages that are techno-typologically distinct from the Levantine Mousterian or the Zagros Mousterian. More specifically, bifacial foliates associated in the FAY-NE 1 assemblage C and Nubian Levallois products in the Dhofar region show affinities with Middle Stone Age assemblages in eastern and northeastern Africa. OSL dates indicate that these recent finds in southern Arabia represent the southern dispersal of early *Homo sapiens* out of Africa during MIS 5 in addition to the northern route to the Levant at Qafzeh and Skhul (Armitage et al. 2010; Rose et al. 2011). Although the southern route hypothesis still needs to be verified with fossil remains in the future, the investigation of the southern and eastern parts of west Asia can contribute greatly to archaeological testing of the southern dispersal route of *Homo sapiens*, linking the population history in west Asia to those in southern and eastern Asia.

Future Directions

Although Paleolithic records in west Asia are well organized on the basis of numerous cultural entities and their chronological sequences, as a result of almost a century of research history, increasing number of new assemblages indicate greater material variability, as exemplified by various non-bifacial Lower Paleolithic assemblages from the Levant and Turkey, Middle Paleolithic assemblages with bifacial foliates in southern Iran and

Arabia, and variable flake-based assemblages of the Levantine Upper Paleolithic. On the other hand, the validity of numerous cultural labels assigned for local Epipaleolithic assemblages is becoming under reexamination. Regardless of the theoretical orientations in the interpretation of cultural entities, their definition and chronological placement continue to be significant issues, particularly along with the progress of radiometric dating methods that allow researchers to make chronological correlations among archaeological assemblages both at the local and regional scales.

Explaining the variability, both synchronic and diachronic, of archaeological entities is a challenging task. Recent accumulation of radiometric dates and paleoenvironmental records led some researchers to reexamine temporal correlations between the occurrences of archaeological entities (Epipaleolithic and Neolithic) and climatic events (Maher et al. 2011), although such examinations would be more difficult for earlier time periods due to greater range of estimated dates. Functional interpretation of material variability has been pursued by several regional studies in Negev, southern Jordan, Azraq, and Wadi Hasa in relation to raw material availability and proximity to water sources, i.e., factors that vary according to daily and seasonal mobility patterns. The continuation of these regional studies should accumulate data regarding the ecological aspects of material variability. On the other hand, the interpretation of lithic industries as representing social groups can add evidence from other material records, such as the association of specific types of bone/antler objects in the Classic Levantine Aurignacian and the composition of imported shells in the Epipaleolithic industries, although the preservation of organic materials can vary under different environmental settings.

In depth studies of particular Paleolithic behaviors include the use of fire, the use of space, hunting behaviors, diets, hunting weapon technology, land-use patterns, burial practices, and creation of symbolic objects. While the synchronic variability of these behaviors can provide insights into the repertoire of adaptive strategy and cultural variability, their diachronic examination can contribute to such issues as the behavioral evolution of early *Homo* populations, the socioeconomic and cognitive aspects of the so-called Upper Paleolithic Revolution and the increasing complexity of subsistence/settlement systems and social structures in the Epipaleolithic period.

Western Europe: Historical Archaeology

Ludomir R. Lozny
Department of Anthropology, Hunter College, The City University of New York, New York, NY, USA

Introduction

Academic archaeology has its roots in the "Great Tradition" of European scholarship (Renfrew 1980: 289; for critical discussion of the "Great Tradition" see Ferguson 2013) of European scholarship (Renfrew 1980: 289). Archaeologists of the eighteenth and particularly the nineteenth century followed that tradition and focused their interests on antiquity for primarily two reasons: The Enlightenment freed antiquity of its biblical and theological context so it became the subject of intellectual scrutiny; antiquity offered spectacular and visible on the surface evidence of the glorious past of the Mediterranean region. Shrouded in mystery to raise interest of the educated and wealthy, research of the ruins of the past guaranteed results, a significant circumstance for privately funded and goal-oriented endeavors. Thus, scholars attempted to describe early civilizations of the classical world such as the Sumerian Empire, the kingdoms of Egypt, Greek city-states, and the Roman Empire. The prevailing at that time concept of archaeology was to accept all evidence of the human past as historic, and such understanding influenced the practice of archaeology in many European countries. Hence the long-lasting relationship between history and archaeology in Europe.

The German archaeologist Carl Schuchhardt (1908: 944 ff. expanded the concept of *Altertumswissenschaft* (science of antiquity) and suggested that also "excavated prehistory," which provides evidence of the past hidden underground, is a part of "real" history. Consequently, prehistoric archaeology became a part of the "Great Tradition." Furthermore, the acceptance of geography and ethnology as professional academic disciplines in

Germany, and later in other European countries, prompted a more systematic and broader scholarly interest in the studies of the past societies. Subsequently, in addition to writing sources, spectacular art objects, and architecture, scholars also accepted less impressive remains of material cultures from the past as historical records recovered by the means of archaeological methods.

Today researchers divide archaeology into two major subdisciplines: prehistoric and historic archaeology. Prehistoric archaeology unravels the story of humanity of at least 2.5 million years and focuses on all aspects of human social life, whereas historic archaeology might seem as an ambiguous subdiscipline, being neither history nor prehistory (Deagan 1988; Small 2011), or prahistory or protohistory, as it is called in some European countries, for instance, in Great Britain, Germany, Poland, and Russia. It is the subject of this essay.

Definition

Historical archaeologists argue about the parameters that define the discipline. The term historical archaeology has several meanings, but it generally relates to researching societies living at times for which we have written records. Thus, it concerns peoples who recorded themselves, and also those who did not have access to script, in writing.

There are generally two understandings of historical archaeology: broader, favored by many European archaeologists, and narrower, followed by some European and American archaeologists. Such duality reminds of Karl Polanyi's 1944:76 44–49 discussion on the two meanings of economics: substantivist and formalist. I shall use this distinction here to explain the two meanings of historical archaeology. The broader "substantivist" understanding refers to the methodology of research. It identifies historical archaeology as a discipline to study all societies who recorded themselves and historical events they either caused, or to which they related, through the use of script supported by archaeological records. According to this view, the range of historical archaeology incorporates all the literate societies from the origins of script until modern times. Therefore, it includes the archaeology of Mesopotamia and Egypt, the Indus River Valley, and southern China, archaeology of the Maya and the Aztecs, classical archaeology of Greece and the Roman Period, medieval and post-medieval archaeology, archaeology of European colonies, urban archaeology, industrial archaeology, etc.

The narrower, "formalist" understanding is strictly about the timeline of processes and events in a specific historical context. In this view, historical archaeology becomes interdisciplinary (bridging disciplinary divides to create new knowledge) and transdisciplinary (use of different sources of knowledge by engaging various stakeholders) field of research that includes a variety of methodologies to examine the world's history since about 1500 CE. For clarity, interdisciplinary approach is to synthesize several disciplines in an attempt to answer research questions or explain a phenomenon; it is not about adding new methodologies to the practice of archaeology. Transdisciplinary research (see also Mode 2 thinking) is about using various sources of knowledge by engaging the interested parties in order to produce new knowledge. On the difference between interdisciplinary and transdisciplinary approach see brief but informative article by Toomey et al. 2015. The definiens here is not just the use of script but the historical context of modernity and the expanding role of Western European countries worldwide and their cultural, primarily economic and political, domination. I follow the chronology of modernity proposed by Marshall Berman (1982: 16–17), who divided modernity into three periods: early (1500–1789), classical (1789–1900 [1914]), and late modernity (1900–1989). According to this narrower meaning, the discipline concerns the post-Columbian (post-Quincentennial) era and emphasizes Eurocentricity and the period of European domination in the world at times of geographic discoveries, the beginnings of mercantilism and the origin of capitalism related to colonialism, and European political domination worldwide. In this respect, scholars agree that historical archaeology relates to primarily the times around and after 1500 CE. I subscribe to such understanding in this article.

The strict definition of historical archaeology is usually explored according to such factors as purpose of research and chronology (American approach) and methodology (European concept), drawing a distinction between the American tradition that defines the subject as "post-Columbian" and the European approach that establishes broader connections with what has been called the "documentary archaeology" of all literate societies. The American definition points out to a specific historical event (1492) as the apical point of the timeline and context, while European colleagues pay attention to the type of sources and methodology. Thus, traditional definitions enlarge the scope of historical archaeology to include all "documentary archaeology" (more on this in Gilchrist 2005), whereas recent definitions focus on specific chronological periods and foci.

Briefly defined, historical archaeology is about studying the evidence and consequences of European cultural (socioeconomic and political) domination from around 1500 CE until recent times. It is chiefly about studying the evidence of broadly understood modernity and its consequences including internal (intracontinental) and external (intercontinental) colonialism of the British, Spanish, Portuguese, French, Dutch, German, and Italian nations. Their interactions and consequences of economic and political domination over regions and peoples worldwide, dated from the end of the fifteenth century (the end of the Middle Ages) to modern times, examined through the use of archaeological and historical methods define the core interests of the discipline. Viewed in such a way, historical archaeology is interdisciplinary and its methodology involves the use of methods to recover and process data on material culture, past ecosystems (historical ecology), language (historical linguistics), and geography (historical geography), but it also dwells on methodologies and theories offered by cultural anthropology (ethnology), sociology, political science, economics, demography, etc. It also becomes transdisciplinary by engaging various stakeholders and their views to inspire conscientization.

In sum, based on the preferred view, the organizing concept for the discipline is either a history of the literate world (broader substantive view) or a history of European political and economic domination and the cultural context of modernity that produced suitable socioeconomic conditions for the origin of capitalism (narrower formalist view). Either way, the unique position of historical archaeology as a research field is the intersection of archaeological data and written records, which allows simultaneous access to variety of sources. Modern Western European historical archaeology crosses the artificial boundaries between classical (Mesopotamia, Egypt, Greece, Rome), biblical, medieval, post-medieval, urban, industrial, underwater, etc., archaeologies. It utilizes common data, methods, methodology, and theory. Historical archaeology also provides the means to study societies who for various reasons have not produced written records of themselves but were impacted by literate cultures.

Historical Background

Historical archaeology emerged in Europe and was exclusively related to researching the classical periods, especially histories of ancient Mesopotamia, Egypt, Greece, and the Roman Empire. Interests in medieval archaeology originated in the last decades of the nineteenth century and intensified, along with post-medieval research, throughout the twentieth century. Medieval archaeology is now well established in Western Europe, but post-medieval and industrial archaeologies are relatively new subdisciplines; both originated and developed within the last 50 years. Significant increase of post-medieval research focusing on the times after 1500 CE occurred in Europe during the 1970s and 1980s and is growing (Fig. 1). Much of post-medieval archaeology sprung out from urban rescue archaeology and studies on material culture. Industrial archaeology developed as "the social history of the working class" and is presently practiced in many Western European countries to address the material evidence for industrialization of the modern world. It deals with still largely intact industrial buildings, factories, and machines of the last two centuries.

Western Europe: Historical Archaeology, Fig. 1 Change in the number of publications regarding historical archaeology, marine archaeology, molecular archaeology, and zooarchaeology, between 1970 and 2008 (After Marriner 2009, Fig. 2)

Thus, if one considers the wider meaning of historical archaeology related to the definition based on methodological aspects, historical archaeology originated in the nineteenth century, whereas the narrower meaning related to the chronological and contextual definition suggests that historical archaeology, although rooted in the tradition of the late nineteenth century archaeology, is a young discipline which matured in the second half of the twentieth century but is still developing and searching for identity. Thus far, Western European historical archaeology has been dominated by the British, German, Dutch, French, Scandinavian, and to some extent American research, and to date there has been little comparative work across the European continent (Gilchrist 2005; Mehler 2013). *Post-Medieval Archaeology* remains the principal society and a journal in Britain that focuses exclusively on the period after 1500 CE.

North American vs European Historical Archaeology

Traditionally, European archaeologists consider archaeology as an auxiliary subfield of history (part of the humanities), whereas in the United States it mostly operates under the umbrella of anthropology (part of the social sciences). Understandably then, European- and American-trained archaeologists view historical archaeology differently (for brief discussion, see, for instance, Mehler 2013). Such distinction is expressed in the definition of the discipline and rooted in its key interests limited by the available sources. Because in North America literate period originated with European colonialism, historical archaeologists study the colonial and postcolonial times, battlefields, slavery, urbanization, mercantilism, industrialization, etc., whereas European archaeologists have a wider range of sources available and thus focus on ancient literate

societies; medieval and post-medieval, industrial, urban, or military archaeology; etc.

Presently, archaeologists view historic archaeology not as an auxiliary subfield of history regarded as a method of obtaining historic facts undocumented in script. They emphasize the claim that it stands on its own. Current developments strongly suggest that the field refocused from studying sheer historical events and from following traditional historical methodology rooted in empirical (logical) positivism to researching historical processes with anthropological methodology that includes evolutionary and comparative outlooks (see Thurman (1998) conversations with Lewis Binford). This trend is common in the United States and is gaining popularity in Europe, although many topics studied by European scholars remain oriented on histories of events rather than processes.

Generally, whether viewed as part of anthropology or history, historical archaeology operates in two distinctive scales: diachronic scale to observe changes over time and synchronic that employs comparative analysis of cultures from the same period. Current historical archaeology, whether European or American, is interested in addressing large-scale processes, visible in global scale. It also dominates the practice of professional or contract archaeology across the globe, as urban development and historic buildings conservation yield massive archaeological data from last centuries. Therefore, even if historical archaeology is viewed as a history with spade, it must not be seen as simply a method of providing data to illustrate historical events. It becomes interdisciplinary and transdisciplinary and not just multidisciplinary. Linked to anthropology and history, it seeks to understand the nature of modern life (cf. Orser and Fagan, 1995: 14) in a larger, global scale. Although it is mostly practiced in Europe and the United States, archaeologists in other regions develop strong interests in this discipline (see Curet 2011; Ikawa-Smith 2011; Politis and Curtoni 2011; Thomas 2011; Sandelowsky 2011; Shimada and Vega-Centeno 2011; Shocoongdej 2011; Small 2011; Thomas 2011; Juwayeyi 2011).

Key Issues and Current Debates

Although traditional Western European historical archaeology focuses on, for instance, acculturation such as the Romanization of Western Europe (Fig. 2), research topics related to Romanization are phrased in terms of imperialism, colonialism, and military expansions. Among new subjects that gain popularity are globalism, cultural domination and resistance, rise of capitalism (commodification), industrialization, economic exploitation, ethnicity, gender, social conflict, identity, etc. Presently, even if topics concern historical events, they are frequently examined in the context of historical process. Such processual outlooks relate to archaeology of colonialism, migrations and culture contacts, archaeology of atrocities, archaeology of power, archaeology of capitalism, archaeology of identity, archaeology of conflict and warfare, industrial archaeology, etc.

One of the most significant among currently discussed topics is the research of societies who otherwise did not record themselves in writing. It relates to studying former colonies in North America, South America, Africa, and South Asia. One of the understudied area is the Hispanic military frontier (Williams 1992: 7) in the New World and its economic and political role. From current studies we learn a great deal about the relationship between the colonizers and the colonized. For instance, Spanish military installations (presidios) were initially economically self-sufficient but after 1830 data reveal greater dependence on European-made products (Williams 1992: 7). It might suggest an increase in local political hostility but certainly point out to changes in economic relationships between the New and Old Worlds. Such research also examines the dependency relations between European early industrial economies and undeveloped colonial peripheries.

The archaeology of African diaspora and the history of slavery very much concerns Europe, Africa, and the Americas. There is also an emerging interest in the British imperial diaspora that unites the historical archaeology of Britain, Ireland, Canada, the United States, India, the

Western Europe: Historical Archaeology, Fig. 2 Mountmaurin, southern France. Gallo-Roman villa. Photo by Ludomir Lozny

Caribbean, Australia, and New Zealand by exploring the legacy of involuntary transportation from Ireland to Australia and contrasting historical and contemporary perceptions of British penal transportation in the two countries. Historical archaeology must not be, however, understood as just the history of European colonial and post-colonial times that dominates the American version of historical archaeology (Fig. 3).

The focus of French historical archaeology (see Bellan and Journot 2011 for a review of recent projects) is on local monographs and long-lasting craft traditions, castles, villas, monasteries, and fields, using the themes of symbolism, knowledge, constraint, power, and conflict. Urban archaeology is emerging and studies of architectural monuments (chateau) are common (Fig. 4). Industrial archaeology and military archaeology (battlefields) increased in popularity throughout Europe (Figs. 5 and 6). Such topics are discussed in relationship to political and economic systems and social arrangements and walls surrounding towns, fields, etc. The social history of walls is not common. It reflects a range of social relations beyond the usually assumed defensive functions, and a conceptualization of walls needs to be readdressed in scholarship. It must include an approach to investigate the social arrangements of space where walls become a part of the landscape as much as buildings, monuments, streets, etc. Some of the European non-city walls include the approx. 150 miles-long Offa's wall (dyke) that separates England and Wales, and Danevirke, a system of ca. 20 miles-long fortifications in the present-day Schleswig-Holstein that originated around 500 CE, has been rebuilt several times and last used in 1864. Such either fortification or boundary markers and certainly noticeable landmarks also exist in other parts of Europe (Samson 1992).

Historical archaeology is, understandably, gaining momentum in Italy, especially its urban fraction and the study of the Renaissance but new trends such as landscape studies become popular. Post-medieval, urban archaeology is also popular in Scandinavia and recently focused on researching post-medieval farmsteads. Studies on cities, countryside, and the relationship

between towns and countryside form the core of historical archaeology in the Netherlands and other Low Countries (Figs. 7 and 8). Archaeology of the great medieval cultural expansions in Western Europe that laid out the foundation for modern Western Europe, especially related to the Franks and Charlemagne and the Norse, are drawing attention of archaeologists and historians.

Theory and Methodology

The epistemology of historical archaeology, as all other archaeologies, is framed within modernity. Historical archaeology, as any other archaeology, has no theory of its own. Whether European or American, until late 1980s - early 1990s it was inherently theory-free. Atheoretical particularism characteristic of the culture history approach was typical for European archaeology and historical archaeology. This is currently changing to incorporate a range of new interpretations and theoretical views. As in history, interpretive approaches prevail over empirically driven explanations and are often mixed with Marxism, especially

dialectical materialism as a popular approach, and structuralism and their epigones such as agency, etc., and other social theories borrowed from sociology, political science, economics, etc. Theories of material culture, and materiality in general, are common to both prehistoric and historic archaeology. Processual, evolutionary-inspired approaches are not very common in Europe while postprocessualism has influenced scholars in several European countries to replace traditional empiricism and positivism. Postprocessual thought gained popularity in Britain and also

Scandinavia has become influenced by postmodern theories. Paul Courtney has recently (2009) reviewed the state of theory in post-medieval archaeology in Europe and concluded that: "...post-medieval archaeology is still largely entwined with medieval archaeology. The main driving force for post-medieval archaeology has tended to be from urban archaeology (...). Rural archaeology has been relatively undeveloped (...). The intellectual roots of post-medieval archaeology across Europe (...) clearly lie in history, though anthropological influences have grown (...)." Fragmentation of practice and theory has become another problem, however. One area in which historical archaeology has begun to realize its unique potentials is that of basic research in archaeology, or the development of middle-range theory to link our observations of the archaeological record to a reasonable approximation of the past events that formed that record (Deagan 1988: 10).

In order to better understand the interest and key issues researched by historical archaeologists and also appreciate the current debates, the following two questions need to be address: How can studying archaeology and history together contribute to better understanding of the human condition, past and present? How can archaeology and history enrich each other? A combination of these two disciplines offers a new and unique methodological perspective to study human culture and in effect produces results that neither one can achieve separately, simply because texts present views on very selective historical events while archaeological data cover a much wider range of events and processes which are better understood and assessed chronologically when supported with written records.

Generally, topics of study within historical archaeology concern both, processes and events. All are concerned about timelines and chronology supported by written sources. Methods to date processes and events are easier in historical archaeology than in prehistoric archaeology because in historical contexts either written sources or specific artifacts, such as coins, produce relatively accurate dates. The problem is to link such finds with the archaeological context in which they occur because coins often date not the time of their circulation but the event of deposition into the archaeological context and therefore suggest a date ex post, but this problem relates to methodology of research and not dating techniques.

There are issues related to the development of new means of production, accumulation of wealth and power, distribution of goods and services, and human sociopolitical organization that can only be understood through the use of methodology that makes reference to both documentary and material accounts of the past conditions. Slavery, imperialism, class formation, cultural syncretism, the manifestation of economic inequality among classes, consumer choice behavior, and accelerated environmental degradation are a few of the related topics that can be accurately described and understood only by a historical archaeological approach, that is, through the use of written records in combination with material evidence (see Deagan 1988: 8 for discussion). Because of its unique methodology to utilize archaeological evidence supported by written sources, historical archaeology also contributes to examining interconnections among various social groups and culture change in a multiethnic context of modern nation-states.

Historical archaeology is diversified in respect to methodology. The practitioners mostly follow the methodology of history but some also engage in studying various topics by employing the anthropological perspective. Because one of the key problems in historical archaeology is to investigate the concurrence of texts and artifacts (see Andren 1998 for discussion), historical archaeology might seem as not fitting in the traditional anthropological framework of American archaeology, but on the contrary, it inevitably establishes links with history and other related disciplines, such as linguistics and art history but also political science and economics. While the availability of documents has sometimes led to a particularistic brand of historical archaeology, in which theory may be underdeveloped, the rich combination of sources has frequently promoted wide-ranging methodological and theoretical innovation. The French contribution to the methodology and

theory of historical archaeology has been the approach identified as *le longue durée*, the history of long-term processes (changes) introduced by Fernand Braudel. It is appropriate to emphasize that due to its unique methodology, historical archeology may contribute to the advancement of theory in archaeology in general.

There is growing use of archaeometry and scientific analysis of artifacts, especially ceramic (composition of paste) or metal objects (physical attributes of metals are used in addition to stylistic analysis to trace the origin of certain objects), but in historic archaeology, certain dating techniques are more useful than others. For instance, absolute dating techniques such as carbon dating is not always recommended in historic contexts because the range it offers (25, 50, or 100 years) might cover a significant portion of the studied period. Dendrochronology seems more appropriate, for it offers a calendric date, but its use is limited by the existence of local tree-ring sequences and the fact that wood is not always present in archaeological sites or does not always date the event but, like coins, suggest ex post dates (the "old wood" syndrome must be kept in mind when using this method). On the other hand, written sources do not document all historical events but selected ones. Therefore, the application of archaeological methods to research traditional historical events and processes for which there is simply inadequate documentation constitutes a valid and important focus in the field and one that boasts the most successful contributions of historical archaeology to date.

Future Directions

Fragmentation of practice and theory has become a significant problem for historical archaeologists during the twentieth century. Modern historical archaeology offers a different outlook and it frequently crosses the interdisciplinary boundaries to utilize various methods, methodology, and theory. As observed by Deagan (1988: 7), in current approaches to the past there is often little difference among studies in historical archaeology, cultural anthropology, and social history.

New methodology of historical archaeology incorporates the use of all kinds of written records, not just narratives but also census data, personal accounts, diaries, etc. The study of material culture has been expanded to also examine the material evidence of space and place which are often manifested in the cultural landscape symbolically. The focus is also on intangible aspect of human culture such as memories, symbolic meanings, etc. All these allow the use of a range of new methods to record and manipulate the data. Therefore, twenty-first century historical archaeology is not just about written records and material archaeological data but it presently relates to oral histories and memories, archaeology of place and space, and indigenous narratives of places. A combination of sources, such as written sources and oral histories (local knowledge), including myths and local legends, are used in designing specific research approaches (Lozny 2006). Significant changes are expected in the use of new theories as a range of theoretical views both processual and post-processual in origin is replacing the atheoretical particularism characteristic of the culture history approach. Historical archaeology must continue to be interdisciplinary and transdisciplinary.

Historical archeology provides good training to critically examine written sources and evaluate how they relate to the archaeological record. In this sense historical archaeology requires very specific methodology in the use of resources which might be or simply are biased. Because it deals with written records, knowledge of various languages, including those presently not in use such as Latin or ancient Greek, is essential (if we accept the broader view of historical archaeology). Landscape archaeology although not exclusive to it became a significant new nondestructive approach to study histories of space (Lozny 2012; and Fig. 9).

There has recently been an attempt to claim a universal character to historical archaeology. The most comprehensive and articulate argument for a global historical archaeology has been formulated by Charles E. Orser (1996), pledging for the definition of the discipline as the study of the modern world, characterized by a single economy that is

Western Europe: Historical Archaeology, Fig. 9 The author and students conducting landscape archaeology project in the Labas Valley, Central Pyrenees. Photo by Ludomir Lozny

colonial, international, and expanding. There are four key concepts defining this new reality: global colonialism, eurocentrism, capitalism, and modernity. The call for a global "modern-world archaeology" addresses the "grand historical narratives" of the last 500 years and specifically such phenomena as capitalism, economic improvement, and consumerism. This approach may, however, channel archaeological thinking into certain more general directions seeking explanations at the global scale and may in effect hamper intellectual advancement in so many other subjects needing research on local scales. Nevertheless, the larger point here is that some consensus between European post-medieval and American historical archaeology is necessary in order to break free from the parochial approach to study the past, as it happened throughout the twentieth century.

Historical archaeology has been, and in some cases still is, politicized and often used for political gains to promote a range of nationalistic agendas (Arnold 1990; Galaty and Watkinson 2004; Lozny 2017), and such use to justify political claims has been common (ample examples from around the world are discussed by various authors in Lozny 2011). Regrettably, such practice will probably continue as the research offered by the social sciences and the humanities is often used for political gains.

Historical archaeologists must also be concerned with ethical practice what constitutes the right conduct and, in this instance, disagreement arises over exactly where ethical responsibilities lie. Historical archaeologists, as all other scientists, must not cross the line that separates scholars from activists; they must honestly report on their findings following the code of scientific conduct and not their personal political agendas. The ethical responsibility here is to the public who are not just the consumers of archaeological knowledge but also our sponsors and any violation of such ethical conduct must be pointed out and censured. The very fact that historical archaeologists engage in an open exchange of ideas about how they affect the people whose heritages they study is an optimistic sign. As discussed by Beaudry (2009), because historical archaeology deals with issues still remaining within memory of many individuals and groups, scholars must follow a specific ethical code. The ethical issues

are relevant to all studies and will continue to be applied to the traditional interests of historical archaeology such as urban archaeology, archaeology of rural areas, archaeology of power, domination and resistance, or material studies. Ethical issues might become particularly significant in the European theater, should the interest grow in studies of phenomena related to the recent history such as forced migration and displacement of large groups in Europe; diasporas; ethnic cleansing and violence; the historical significance of the two most potent and vicious social systems of the twentieth century – fascism and communism; war atrocities, social movements; and also larger social phenomena such as colonialism and post-colonial environment evidenced in multicultural societies in Europe and elsewhere, the significance of cultural heritage in multiethnic societies and its relation to sustainable development, etc. These are the most pressing issues to be studied by historical archaeologists in the twenty-first century.

Historical Archaeology in the Academia

Historical archaeology is taught at several European universities in Great Britain, Germany, France, Italy, Spain, the Netherlands, and Belgium, and many aspects are also covered in classes related to medieval archaeology or art history. The academic aspect of historical archaeology would require a separate study and thus is not the concern in this essay.

Historical Archaeology and Preservation (Conservation)

Historical archaeology forms a core of many culture managements and preservation (conservation) institutions and services in western Europe, such as English Heritage (Historic Building and Monuments Commission for England), French *Institut National de Recherches Archéologiques Préventives* (INRAP), German *Denkmalschutzämter* and *Stadt-und Kreisarchäologien*, Dutch *Rijksdients voor het Oudheidkunding Bodenmonderzoek* (ROB), Swedish *Riksantikvarieämbetet*, and offices of the Italian *Ministero per i Beni e le Attività Culturali* and Spanish *Instituto del Patrimonio Cultural de Espana* to name a few. These are the strongholds of Western European historical archaeology as places of research and employment.

Western Roman Provinces, Archaeology of the

Stacey McGowen
Regent's Park College, University of Oxford, Oxford, UK

Introduction

By the end of the first century CE, all of the modern countries of Western Europe up to the Rhine river, including Spain, Portugal, France, Belgium, the Netherlands, Germany, Switzerland, and much of Britain, had been incorporated into the Roman Empire. They eventually became the Roman provinces of Hispania Baetica, Hispania Lusitania, Hispania Tarraconensis, Gallia Narbonensis, Gallia Aquitania, Gallia Lugdunensis, Gallia Belgica, Raetia, Noricum, Germania Superior, Germania Inferior, and Britannia (Fig. 1).

Greco-Roman goods had been flowing into most of these areas before their formal incorporation into the empire, and after the conquest and the establishment of the provinces, some areas accepted Roman and/or Mediterranean traditions more than others. This is particularly true in the provinces of Gallia Narbonensis and the eastern and southern parts of the provinces of the Iberian Peninsula, particularly because of the presence of Greek and, in the case of Spain, Phoenician colonies that predated incorporation into the empire. Even so, it is clear that Mediterranean goods were circulating in the entire region, even in Britannia, prior to their official conquests.

Key Issues

Urbanism

It was in the provincial towns and cities where much of the cultural interaction between the indigenous populations, merchants, soldiers, and Roman officials took place. Here patrons could expect more people to witness their benefactions, and so most acts of euergetism occurred in these locales. It was also in urban locations that members of the indigenous population became familiar with Greco-Roman traditions.

The Roman-period towns of the western provinces can be divided into four categories, *coloniae*, *municipia*, *civitas* centers, and *vici*, of roughly descending importance. In most instances, *coloniae* consisted of settlements of Roman veterans, but some cities, such as *Eburacum* (York) in Britannia or *Vesontio* (Besançon) in Germania Superior, were promoted to this status. Some towns of considerable size fell into none of these categories, for example, *Aquae Sulis* (Bath), which seems to have been more of a resort town (Dark 1993). Moreover, these designations did not always reflect the importance of a town. *Mogontiacum* (Mainz), for instance, an important legionary base, the capital of Germania Superior, and an important economic center along the Rhine was only a *vicus* until its promotion to a *municipium* in the fourth century CE. The large urban centers, primarily the provincial capitals and the colonies, have received the greatest level of archaeological scrutiny, but particularly since 1960s and 1970s, attention has increasingly turned to small towns and other types of nucleated settlements (Burnham and Wacher 1990).

The provincial capitals had a particularly important role to play in the diffusion of Roman traditions. The capitals of the Iberian provinces were *Emerita Augusta* (Mérida) in Hispania Lusitania, *Corduba* (Córdoba) in Hispania Baetica, and *Tarraco* (Tarragona) in Hispania Tarraconensis. Those of the Gallic provinces were *Burdigala* (Bordeaux) in Gallia Aquitania, *Durocortorum Remorum* (Reims) in Gallia Belgica, *Lugdunum* (Lyon) in Gallia Lugdunensis, and *Narbo Martius* (Narbonne) in Gallia Narbonensis. The capital of Germania Inferior was *Colonia Claudia Ara Agrippinensium* (Cologne), and the capital of Germania Superior was *Mogontiacum* (Mainz). Although the capital of Britannia was originally *Camulodunum* (Colchester), eventually *Londinium* (London) became the home of the provincial governor. The capital of Noricum was *Virinum*, which was not even officially founded until 50 CE. Lastly, while it does not appear to have been the original

Western Roman Provinces, Archaeology of the, Fig. 1 Map of the western provinces. Public domain

provincial capital of Raetia, by the second century CE, *Augusta Vindelicum* (Augsburg) had assumed this role.

In addition to the provincial capitals, other *coloniae* and *municipia* functioned as important urban centers. The Iberian provinces had 27 *coloniae* and as many as 37 *municipia* altogether (Curchin 1991: 103–22; Fear 1996: 63–104). Many more *coloniae* were founded in western Spain because this part of the region was not as urbanized from the start. In the south and east, the important cities of *Gades* (Cádiz), *Carthago Nova* (Cartagena), and *Emporiae* (Empúries) predate formal Roman activity in the

region by centuries. *Gades* (Cádiz), founded by the Phoenicians perhaps as early as c. 1100 BCE, was the oldest city in Spain. *Carthago Nova* (Cartagena), established by the Carthaginians in 223 BCE, was described centuries later by Livy as *opulentissima omnium in Hispania* – the richest of all the cities in Spain (Liv. 26.48). *Emporiae* (Empúries) was founded in the middle of the sixth century BCE by Greeks from the colony of *Massilia* (Marseille). Despite these examples, Spain was not particularly urbanized prior to incorporation into the Roman Empire.

On the other side of the Pyrenees, the earliest of the colonies were founded in the southern part of the region. By the end of the Augustan period (27 BCE to 14 CE), veteran colonies had been established at *Narbo Martius* (Narbonne), *Arelate* (Arles), *Baeterrae* (Béziers), *Arausio* (Orange), *Forum Julii* (Fréjus), most likely *Noviodunum* (Nyon), *Augusta Raurica* (Augst), *Carpentoracte Meminorum* (Carpentras), and *Lugdunum* (Lyon), and possibly even *Valentia Julia* (Valence) and *Vienne* (Vienna). It was not until the middle of the first century CE and beyond that colonies were founded in the north, with veteran colonies at *Colonia Claudia Ara Agrippinensium* (Cologne) founded under Claudius (r. 41–54 CE), possibly at *Aventicum Helvetiorum* (Avenches) under Vespasian (r. 69–79 CE), and *Vetera* (Xanten) under Trajan (r. 98–117 CE).

In order to determine the size and importance of the urban centers in the Gallic provinces, Goudineau ranked them on a set of 35 different criteria, including size of territory, number and scale of monumental structures, degree of urban planning, level of industry, and legal status, among others (Goudineau 1980). Based on his analysis, he identified the 18 largest towns in the region and divided them into four groups: first, *Lugdunum* (Lyon), *Narbo Martius* (Narbonne), *Nemausus* (Nîmes), *Augusta Treverorum* (Trier), and *Vienne* (Vienna); second, *Arelate* (Arles), *Burdigala* (Bordeaux), *Augustodunum Aeduorum* (Autun), and *Durocortorum Remorum* (Reims); third, *Vasio Vocontiorum* (Vaison), *Mediolanum Santorum* (Saintes), *Aventicum* (Avenches), *Baeterrae* (Beziers), and *Arausio* (Orange); and finally *Forum Julii* (Fréjus), *Aquae Sextiae* (Aix-en-Provence), *Divodurum* (Metz), and *Tolosa* (Toulouse). Although not part of Goudineau's study in the two Germanies, *Colonia Claudia Ara Agrippinensium* (Cologne) developed into the most successful commercial center and was perhaps second only to *Lugdunum* (Lyon) in the continental provinces (Drinkwater 1983: 130).

Unfortunately, no such study has been undertaken in Britain, but it is evident that the island had fewer large urban centers than the continental provinces (Mattingly 2006: 260–3, 289). There were only four *coloniae*, *Camulodunum* (Colchester), *Glevum* (Gloucester), *Lindum* (Lincoln), and *Eburacum* (York), and the only known *municipium* was *Verulamium* (St. Albans). *Londinium* (London) demonstrates, however, that this system was not rigid because, although the capital and the most important city in Britannia, no firm evidence has survived to indicate that it ever became a *colonia*.

Noricum had only one colony, *Ovilava* (Wels), a town that was elevated to this status and did not have any veterans (Alföldy 1974: 86–96). This lack of *coloniae* seems to indicate that not many Roman citizens ever immigrated to the province. In addition to this colony, the province had eight *municipia*, a particularly large number of towns given that much of the province consisted of mountainous and uninhabited areas.

Very few towns of status are known in Raetia. Its capital, *Aelium Augustum* (Augsburg), is the only confirmed *municipium*. Although Tacitus does mention a *splendissima Raetiae provinciae colonia*, a most splendid colony of the province of Raetia, unfortunately he does not give the name of the town (*Germania* 41). It seems, however, that the two most important towns in Raetia were *Curia* (Chur) and *Tridentum* (Trent).

Although all of the western provinces had such urban centers, they were unevenly distributed. Some areas, such as Normandy and Brittany in France, Wales, and southwestern England, showed hardly any urbanization. Likewise, these regions had little in the way of Roman-style development, with, for example, few Roman-style architectural features, inscriptions, or sculpted

monuments (Mattingly 2006: 296, 509; King 1990: 106, 120).

The Countryside

Despite the urban development that took place after the incorporation of the region into the Roman Empire, the rural population in all parts of the region always exceeded the urban one. In Britannia, for example, the urban population has been estimated to have been no more than 200,000 compared to a rural population of 1.6 million (Mattingly 2006: 256). The types of settlements in the countryside varied widely, and the ways in which they are defined alter our understanding of their development distributions. Moreover, these areas have not often been subjected to the same level of archaeological scrutiny as the urban centers.

The most outstanding archaeological feature of the countryside is the villa. The term villa is complicated. Here the term indicates a rural structure with some Roman-style features, such as rectilinear architecture, stone or ceramic building materials, mosaics, and public baths, that may also have had productive elements including grape and olive presses or grain dryers.

The placement of rural residences was not unrelated to the placement of the urban centers, largely because of the economic opportunities they provided to agricultural producers but also the importance of landholding to the urban elites. Clusters of villas are known around, for example, many of the towns of Noricum, including *Virunum*, but especially *Juvavum* (Salzburg). Such patterns are not entirely straightforward because, for example, very few villas are located near *Londinium* (London), the largest city in Britannia, while many appear around *Cunetio* (Mildenhall, Suffolk), a relatively small settlement.

The heyday of the villa in most parts of the region was in the early fourth century CE, but their number and size varied temporally. For instance, in Britannia the villas of the first century, such as the large and extravagantly decorated villa at Fishbourne (West Sussex), averaged more than 2,000 m^2 in built area (Cunliffe 1971). Such villas were located almost exclusively in the southern part of the province. Over the course of the following three centuries, villas spread across a wider area of the south, but while they were increasing in number, they were at the same time decreasing in size. Villas are essentially absent in some parts of Britannia, particularly Wales and the military zone in the north near Hadrian's Wall, particularly in the modern counties of Cumbria, Durham, Northumberland, and Lancashire. While it seems possible that the heavy military presence in these areas stifled economic development, it is equally if not more likely that in these areas the segment of the population wealthy enough to construct villas felt no need to display their wealth in this way.

Villas are abundant in the Gallic provinces, especially in the area from across Gallia Belgica southwest across Gallia Lugdunensis to Gallia Aquitania (King 1990: 92–7). The regions of Picardy and southern Aquitaine have been particularly well studied thanks to aerial photography undertaken in the 1960s and 1970s CE. Although many different arrangements existed for the villas in this area, one of the most popular types consisted of a main residence building with a forecourt adjacent to a large rectangular courtyard, sometimes as large as two hectares, which was surrounded by subsidiary buildings. Such villas are known in Picardy, for example, at Warfusée-Abancourt, but also in Aquitaine at Montmaurin and Chiragan and further afield at Anthée, Echternach, Otrang, Oberentfelden, Seeb, Levet, and Noyers-sur-Serein. Despite the widespread nature of this style of villa, certain regions had their own preferred arrangements. An example is the "hall villa," peculiar to the Germanies and northern Gallia Belgica, which had larger open rooms instead of clusters of smaller ones, while the villas of Gallia Narbonensis were much more like their Italian counterparts, with a residence wing and often an area with facilities for the production and storage of both olive oil and wine.

Architecture

Although most of Spain, and particularly the south of France, was incorporated into the Roman Empire by the late second century BCE,

in both areas the development of monumental architecture did not occur until the Augustan period (Ward-Perkins 1981: 219). After the Augustan period, towns throughout the region contained Roman-style structures, including fora, aqueducts, baths, and entertainment facilities.

The forum complex at *Augusta Raurica* (Augst), dating from the mid-second century, is typical of city centers and public architecture throughout the western provinces (Ward-Perkins 1981: 220–1). The monumental core of the town occupied three entire blocks of the city's grid and consisted of a basilica, forum, and a temple, which together formed a single unit, unified by a series of porticos. As is typical in the western provinces, the basilica ran transversely across one end of the space of the forum, while the temple faced it at the opposite end. Similar complexes can be found at *Lutetia* (Paris), *Lugdunum Convenarum* (Bertrand-de-Comminges), and *Virinum*, just to name a few in the continental provinces. In Britain, the pattern was altered somewhat, often with the omission of the temple, as at *Venta Silurum* (Caerwent), Caistor, *Calleva Atrebatum* (Silchester), and *Viriconium Cornoviorum* (Wroxeter).

Some of the finest Roman-period architectural elements to survive in the western provinces revolved around water (Sear 1998: 210–3, 217; Ward-Perkins 1981: 214–8, 224–5). In fact, perhaps the most impressive architectural elements in Spain were the aqueducts and bridges, including the bridge over the Tagus river (Tajo) in Alcantara, the highest in the Roman world, as well as the aqueduct bridges at Segovia and *Tarraco* (Tarragona). The most famous of the aqueduct bridges in the western provinces is, however, the Pont du Gard (Fig. 2), which was part of the channel that provided water to *Nemausus* (Nîmes). Most aqueducts were underground and lacked these dramatic aqueduct bridges. On the continent, *Augusta Raurica* (Augst) had an aqueduct, and *Colonia Claudia Ara Agrippinensium* (Cologne) had two, while *Aventicum* (Avenches) had at least six (Carroll 2001: 50–1). With the exception of a timberlined channel in *Cambodunum* (Kempten), no aqueducts

Western Roman Provinces, Archaeology of the, Fig. 2 The Pont du Gard (©S. McGowen)

have survived in Raetia (Herrling 1943: 119). In Britain, the nature of the terrain as well as the availability of water also made aboveground channels largely unnecessary (de la Bédoyère 2001: 213–4).

The water from these aqueducts was used for many purposes, one of which was baths (Ward-Perkins 1981: 233–6; Carroll 2001: 49–50; de la Bédoyère 2001: 38–9, 104–8). Towns of any significance had public baths, sometimes several sets. Some bathing establishments in the western provinces, for example, those at *Glanum* (St.-Rémy), have an arrangement of the traditional bathing rooms (*frigidarium*, *tepidarium*, *caldarium*) along the edge of *palaestra* as found in Pompeii, for example. An alternative design seems to have developed in the Gallic provinces. In this case, the bathing rooms were arranged linearly, as in the Great Southern Baths at *Conimbriga* (Condeixa-a-Velha) in Hispania

Lusitania (Ward-Perkins 1981: 217–8). Interestingly, these baths replaced an Augustan-period complex of the traditional Pompeian type. Baths fed by springs were also common architectural features in the western provinces. These types of baths often included numerous plunge pools. Such baths are known at *Ivaonum* (Évaux) and *Rubiacum* (Royat) in Gallia Aquitania, Badenweiler in Germania Superior, Les Fontaines Salées in Gallia Lugdunensis, and Amélie-les-Bains in Gallia Narbonensis, but perhaps the best surviving set is found at *Aquae Sulis* (Bath) in Britannia.

Structures used for entertainment – theaters, amphitheaters, and circuses – were also particularly important to the development of Roman-style architecture in the region. The western provinces and Gaul in particular are home to some of the earliest known theaters outside of Italy (Sear 2006: 97–102, 196–254, and 258; Ward-Perkins 1981: 230–2). Several theaters are known in the Gallic provinces, including those at *Arelate* (Arles), *Lugdunum* (Lyon), and one at *Arausio* (Orange), the latter of which is preserved almost entirely. The largest of the Gallic theaters, with a capacity of c. 7,000 people, was in *Augustodunum Aeduorum* (Autun). The Iberian provinces had at least 15 theaters, including those at *Italica* (Santiponce), *Emerita Augusta* (Mérida), *Tarraco* (Tarragona), *Saguntum* (Sagunto), and *Acinipo* (Ronda la Vieja), most of which were constructed in the first and second centuries CE (Keay 1988: 125). In the Germanic provinces, theaters have been discovered at *Augusta Raurica* (Augst), *Aventicum* (Avenches), *Mogontiacum* (Mainz), *Nida* (Heddernheim), *Lopodunum* (Ladenburg), *Epomanduodurum* (Mandeure), and Lenzburg, all of which were built of stone with the exception of the one at Heddernheim (Carroll 2001: 51–2). In contrast, only three theaters have been identified in Britannia; those at *Durovernum Cantiacorum* (Canterbury), *Camulodunum* (Colchester), Gosbecks, and *Verulamium* (St. Albans) have been identified (de la Bédoyère 2001: 102–4). It is likely, however, that *Londinium* (London) and the other *coloniae* also had theaters. In Noricum, theaters are known at *Virunum* as well as at *Carnuntum* (Pfaffenberg). So far no theaters have been identified in Raetia.

Although not as numerous as theaters, several amphitheaters existed in the western provinces. Many were made of wood, as at *Aventicum* (Venches) or *Xanten* (Vetera); in Britannia, most consisted of earthen embankments with timber or stone revetments (de la Bédoyère 2001: 99–102). Although most were located in the larger towns, an amphitheater has been identified using aerial photography at *Venta Icenorum* (Caistor St. Edmund), one of the smallest *civitas* centers in Britain. In the western provinces, circuses were the rarest of the entertainment structures (Keay 1988: 120–3; King 1990: 80–82). The Gallic provinces had only five, and the only known example in Britannia is at *Camulodunum* (Colchester) (Crummy 2005).

With a few important exceptions, imperial benefaction was rare in the western provinces. Euergetism by provincials led to the construction of public buildings, but in the western provinces, competitive building by members of the elite was comparatively rare. In Britannia, most public benefactions were actually made by outsiders (Mattingly 2008). For example, a certain Lucius Viducius Placidus built an arch and a gateway in York, although he appears to have originated from the area around Rouen (*AE* 1977.512; *AE* 1983.643).

Infrastructure

As true of most of the Roman Empire, the western provinces had well-developed infrastructure. These regions had pre-Roman roads, as, for example, the Venetic road linking *Julium Carnicum* (Zuglio) with a settlement on the Gurnia River in Noricum. After the conquest of each region, however, extensive road networks developed throughout the provinces. Although originally constructed for the military, once in place they were used for civilian purposes, speeding communication and facilitating the transportation of goods. These roads were also powerful symbolically, as they marked a territory as unquestionably Roman.

In the Iberian provinces, many of the roads followed the major rivers such as the Ebro,

Tagus, and the Duero and divided the tribal territories. The so-called *Camino de la Plata* started as just such a road and eventually became a major artery between *Asturica Augusta* (Astorga) and *Emerita Augusta* (Mérida) (Keay 1988: 49). The Via Heraclea (later the Via Augusta), one of the most important roads in Spain, ran along the coast and linked Spain with both Gaul and Italy. The earliest roads in the central European provinces were constructed in the south. In the late second century BCE, an important road linking the Pyrenees and the Rhône was established (King 1990: 39). Then, in the later first century BCE, the road network was extended northward: initially from *Lugdunum* (Lyon) to the Moselle, then to *Colonia Claudia Ara Agrippinensium* (Cologne) and the Atlantic, as well as east-west through *Bagacum* (Bavay) to the Atlantic coast (King 1990: 55–6; Carroll 2001: 32–3; Drinkwater 1983: 124). An important route eventually developed along the west bank of the Rhine to the North Sea, passing through *Mogontiacum* (Mainz).

Similar roads, which undoubtedly began as military supply routes, also crisscrossed Britannia. The three most important roads in Britannia were Watling Street, which extended from London to Chester and points north, the Fosse way, running from Exeter to the colony at Lincoln, and Ermine Street, which went from the south through London and on to Lincoln and then on to York (Mattingly 2006: 134, 142–3). In Noricum, the most important Roman road connected Aquileia with the Tagliamento valley. This thoroughfare crossed the Alps from Italy at the Sella di Camporosso (Saifnitzer Sattel) to *Virinum* where it turned north to *Ovilava* (Wels) and on to the Danube River (Alföldy 1974: 11–3). In Raetia, the southern part of the province was not as well equipped with roads as the north, and certainly this reflects the military origin of the road network (Herrling 1943: 100–16). Numerous roads also fed into the capital at *Augusta Vindelicum* (Augsburg) from all directions.

Although these networks were extensive, travel by road was slow and expensive, and so wherever possible travel by water was preferred. In the Iberian provinces, grain, olive oil, and minerals were transported along the Guadalquivir River from *Corduba* (Córdoba) to points downstream and onto seafaring vessels. Likewise, one of the reasons for the success of *Londinium* (London) was its placement not only at the hub of the road network but also at the navigable end of the Thames. *Lugdunum* (Lyon), too, was a hub in the road network as well as a point where riverboats could travel north up to the Saône to *Cabillonum* (Chalon-sur-Saône). *Arelate* (Arles) also gained importance from its location at the mouth of the Rhône, where seagoing vessels could transfer goods onto riverboats. Additionally, the Rhine and the Danube were navigable and served as major trade routes in the Germanic provinces, Noricum, and Raetia.

Art

Pottery, jewelry, metalwork, and other smaller-scale objects could certainly qualify as art objects. Gaulish Samian ware, with its major production center at La Graufesenque near Millau, was exported throughout the western provinces (Bémont and Jacob 1986). The major artistic outlets were, however, wall painting, mosaic, and sculpture.

Before the Roman period, no tradition of wall painting or plasterwork existed in the area that would become the western provinces. In the Roman period, wall painting was almost ubiquitous in the homes, temples, and public buildings, but unfortunately it has not survived well. What has survived has often been removed from its context and, perhaps more detrimentally, divided between different museums and collections. No doubt the spread of this type of wall decoration was uneven, but the limited remains make a thorough analysis of the pattern of diffusion difficult.

All of the four Pompeian Styles appear in the western provinces (Ling 1991: 168–74; Henig 1995: 118–20). The Pompeian Second Style decoration appears in four houses in *Glanum* (St.-Remy), including the so-called House of Sulla, which dates to the 40s BCE. Architectural illusionism and trompe-l'œil, hallmarks of the Second Style, also appear in wall painting from the Dover Painted House, a second-century building at Southwark in Britannia. The Third Style was especially popular in the western provinces. An

example dating to the mid- to late Augustan period from Magdalensberg shows Dionysus and several Greek heroines on red backgrounds, and the mature Third Style appears at a villa in Commugny in Switzerland, with similar examples at both *Vesunna* (Périgueux) in Gallia Aquitania and *Aventicum* (Avenches) in Gallia Belgica. The Fourth Style, though often simplified with less fantastical architecture, is particularly popular in Gaul, the Germanies, and the Iberian provinces. Some instances contain extra detail not usually found in Italy. For example, in the baths at *Virinum*, foliage consisting of flowers and fruit containing birds and other objects took the place of the typical candelabras, and at *Asturica Augusta* (Astorga) in Hispania Tarraconensis, attributes of various gods and goddesses, such as the winged hat of Mercury or the lyre of Apollo, were introduced. Although only two, these cases demonstrate the type of excess detail and creative use of motifs that could be found in provincial wall painting.

After the destruction of Pompeii, wall painting continued in Italy as well as in the provinces. At a house at Leicester appears a trompe-l'œil podium together with fine and delicate architectural decoration typical of the Pompeian Fourth Style. Such eclecticism is fairly typical of wall painting in the second and third centuries. At this same time, mythological iconography became increasingly rare. Two fine exceptions, both dated to the Antonine period (mid-second century CE), survive in Germany. At *Augusta Treverorum* (Trier), Jason and Medea appear in the central panel of the so-called green wall, and at a frontier fort in Echzell, a panel containing an image of Fortuna handing over a cornucopia to Hercules is flanked by a pair of Cretan scenes: Daedalus making the wings of Icarus and Theseus killing the Minotaur. It also appears that particular patterns were preferred in certain contexts. For example, curvilinear motifs were favored on ceilings, as, for example, at Hölstein and Bösingen in Switzerland. Dating to late second or early third century CE, both ceilings are decorated with intersecting circular garlands, similar to ceiling paintings in the Neronian *Domus Aurea* in Rome. Paintings from *Augusta Treverorum* (Trier), capital of the prefecture of Gaul under the tetrarchy, demonstrate the fine quality possible in provincial painting. One room in particular, perhaps part of an imperial residence, has an elegant ceiling decorated with portrait busts and cupids. Though the identity of the portraits is debated, the execution of the paintings is highly naturalistic, with bodies well proportioned and drapery fully plastic. Such features were, however, short lived. With the increasing Byzantine influence, illusionistic architecture was replaced by patterning in bright, contrasting colors as, for example, at Lullingstone and *Venta Silurum* (Caerwent) in Britannia. Moreover, pagan iconography gradually diminished in favor of Christian subjects, such as the *orantes* from the villa at Lullingstone.

As with painting, no native tradition of decorated pavements existed (Ling 1998: 61–76; Dunbabin 1999: 73–87, 144–59). Fragments of pebble mosaics perhaps dating to the fifth and fourth centuries BCE have survived at *Cástulo* (Cazlona) in southern Spain, but otherwise the tradition is largely nonexistent. Early mosaics are closely tied to Italian prototypes, but as local mosaicists trained others, regional workshops developed with their own localized and distinctive styles. For example, a school of mosaicists operated in the Rhône valley and had production centers at *Lugdunum* (Lyon) and *Vienna* (Vienne); the development of regional workshops is particularly well documented for Britannia (Smith 1965).

Early examples of decorated floor coverings come in the form of *opus signinum* pavements from *Emprion* (Ampurias), *Glanum* (St.-Rémy), and *Massalia* (Marseille). Black and white mosaics, which were predominant in Italy during the early Imperial period, have been found throughout the region, with some fine early examples known at *Emporiae* (Ampurias) and *Forum Julii* (Fréjus) on the continent, and also at the large early villa at Fishbourne in Britannia.

In addition to the black and white mosaics, figured mosaics, primarily mythological in nature, also appeared. Literary or academic themes were particularly popular in the area of the Mosel Valley and the Rhineland, coming from workshops centered on *Augusta Treverorum* (Trier) and *Colonia Claudia Ara Agrippinensium* (Cologne).

Such mosaics often represent the Muses or important artists and authors. For example, a mosaic from *Augusta Treverorum* (Trier), known by the name of its artist, Monnus, depicts the Muses with literary figures such as Homer and Aratus as well as a gallery of the greatest Greek and Latin authors including Hesiod, Menander, Cicero, and Vergil (Fig. 3). One example of such a literary mosaic has been found at Low Ham in Britain. This mosaic depicts episodes from book four of the *Aeneid* in a narrative sequence. On the whole, however, depictions of Roman legends are rare. Scenes from daily life, such as chariot racing, gladiatorial combat (Fig. 4), and hunting also appear, although they too are relatively uncommon.

Little tradition of sculpting in stone existed in the western provinces before incorporation into

Western Roman Provinces, Archaeology of the, Fig. 3 Vergil panel from the Monnus mosaic at *Augusta Treverorum* (Trier) (©S. McGowen)

the empire. It is possible, however, that wood could have been the preferred medium and that it simply does not survive. Nevertheless, after formal incorporation, use of stone for sculpture increased dramatically. In addition to sculpture in stone, bronze sculpted monuments did exist throughout the region, for example, the head of Hadrian (r. 117–138 CE) from the river Thames in *Londinium* (London) and the head of Minerva from the sanctuary of Sulis Minerva in *Aquae Sulis* (Bath) (Fig. 5). Because of the inherent value of bronze, which can be easily melted down and recast, they have not survived well.

Stone sculpture appeared in four main contexts in the western provinces – private, civic, funerary, and sacred. Sculpture adorned some homes and villas throughout the region (Stirling 2005: 29–90, 190–5). For example, at the villa in modern-day Lullingstone in Britannia, two portrait busts made of Greek marble were discovered, and in a private home in *Limonum Pictonum* (Poitiers) in Gallia Aquitania was found a statue of Minerva in a Greek archaic style. An astounding collection of sculptures was also found at the villa in Chirgan in the province of Gallia Aquitania about 60 km from *Tolosa* (Toulouse).

Western Roman Provinces, Archaeology of the, Fig. 5 Bronze head of Minerva from *Aquae Sulis* (Bath) (©S. McGowen)

Sculptures such as these certainly said much about the wealth and status of their owners. Sculpture was, however, more prevalent in public contexts. Funerary monuments, from monumental structures such as the Mausoleum of the Julii at *Glanum* to smaller stelai such as the tombstones of M. Favonius Facilis from *Camulodunum* (Colchester) and L. Cantius Secundus from near St. Leonhard in Noricum, were erected with varying density throughout the region. Public places, such as the fora at *Lugdunum* (Lyon) or *Tarraco* (Tarragona); the theaters at *Arausio* (Orange), *Tarraco* (Tarragona), and *Italica* (Santiponce); or the baths at *Virinum*, were decorated with sculpture. Finally, architectural sculpture and sculpted votives appear at numerous sacred sites, including the sanctuary of Sulis Minerva at *Aquae Sulis* (Bath), decorated with a sculpted pediment depicting a fierce, mustached male gorgon, or the sanctuary of Hercules at Deneuvre, where more than 50 reliefs and freestanding statues of the god have been discovered (Fig. 6).

Much sculpture from the western provinces is of high quality and naturalistic, in keeping with the Greco-Roman traditions. Most works from Lyon (*Lugdunum*) and *Vienne* (Vienna), catalogued in the *Nouvel Esperandieu* series, are naturalistic and entirely Greco-Roman in style (Darblade-Audoin 2006; Terrer 2003). Moreover, the sculpted heads of Jupiter Ammon from the forum at *Tarraco* (Tarragona) seem directly inspired by the Forum of Augustus at Rome and are executed with a high level of skill. Much of the Roman-period sculpture from the western provinces is not of such high quality. Instead, in contrast to Greco-Roman naturalism, it tends to be highly schematic, displaying a so-called Celtic style, hallmarks of which are flowing hair, oversized heads and eyes, and fondness for patterning. (Green 1998) has even suggested that such stylistic features may be "...conscious attempts by indigenous populations...to make a positive and independent statement..." In contrast, (Johns 2003) has presented a strong counterargument advocating that the skill of the artists and the nature of the material highly influenced style, often regardless of the desires of the patrons or even the intentions of the artists.

Religion

Not much is known of religious traditions in the area of the western provinces prior to incorporation of the region into the empire. That it was polytheistic is clear, but almost nothing is known about the names of the deities, and those that are known come from Roman-period sources. Pre-Roman religious practice does not seem to have involved temples generally. It does seem to have been concentrated around natural features such as rivers, springs, and groves, as, for example, described by Lucan in his account of Caesar's campaigns in Gaul (Lucan, 3.394-452). Based on the quantity of objects discovered in sacred contexts, it is apparent that the practice of making dedications to the gods was widespread.

The invasion and the subsequent incorporation of these regions led to an influx of new people who brought with them the gods of the official Roman state religion, including the Capitoline Triad of Jupiter, Juno, and Minerva (Fig. 7), and it was effectively a requirement that each *colonia* has a temple for these gods. The most important part of official religion in the provinces was, however, the imperial cult. Each province had its own provincial temple, where representatives of the population gathered every year to make offerings and take part in ceremonies. Such temples existed at *Tarraco* (Tarragona), *Emerita Augusta* (Mérida), *Narbo Martius* (Narbonne), *Lugdunum* (Lyon), and *Camulodunum* (Colchester) (Fishwick 1987: 82–8, 235–46). Early phases of the provincial cult in the west usually consisted of an altar provided for the worship of living emperors, while temples were reserved for the cult of the deified, deceased emperors. Although the precise form of these temples is not always known, it does appear that the types of temples used for these official cults were very much Roman in form. The introduction of these official cults into the provinces illustrates how the Romans used religion for political ends: official religion and the imperial cult in particular served to unify the diverse populations of the empire (Allason-Jones 2008: 120–1).

Not all gods were, however, new. Pre-Roman gods were incorporated into Roman religious

life in three main ways. In some instances, a Roman deity took over completely. For example, while pre-Roman religious activity occurred at Uley in Britannia, in the Roman period, Mercury became the chief deity of the sanctuary. Here the Roman messenger god took on a martial capacity, as demonstrated by the dedication of model spears to alongside caducei. In some instances, a deity from the Roman pantheon was paired with a pre-Roman one. For example, the Celtic deity Sulis was paired with Roman Minerva at *Aquae Sulis* (Bath) in Britannia, and in *Aquae Granni* (Aachen) in Germania Inferior, the Roman god Apollo was paired with the Celtic Grannus. In some instances, however, the pre-Roman deity remained and was sometimes venerated with inscribed and sculpted dedications, a Roman religious tradition. Generally, such deities are referred to local deities. Coventina, for instance, had a center of worship at *Brocolitia* (Carrawburgh) on Hadrian's Wall, and for a long time, she was considered a local deity. Altars dedicated to this goddess have also been found in northern Spain. It is not entirely clear whether her worship traveled from Britain to Spain or Spain to Britain, and adding to the complication, all of the devotees whose ethnic origin is known are Germanic (Allason-Jones 2008: 118–9). Thus, the identification of deities with non-Roman names as local is more complicated than it may first appear.

This same sort of blending is also apparent in religious architecture. A distinctive type of temple existed in the western provinces, particularly northern Gaul and Britannia. Though some variation of shape did occur, they consisted primarily of a square central cella surrounded by a concentric ambulatory or passageway. Such temples are largely confined to civilian areas. In Britannia, for example, most of the more than 50 temples of this type have been discovered in the southern and eastern parts of the province away from the military areas in the north. Worship in the military area, by contrast, was marked by the erection of inscribed stone altars, which are largely absent in the rest of Britain.

The Military and the Borders

The military also left an enduring archaeological mark on the western provinces, particularly the frontier regions of the Germanies, Britannia, Noricum, and Raetia but also northwestern Spain (Hanel 2007). Throughout these areas, permanent bases were constructed for both the legionary and auxiliary forces. Camps of the early empire were often polygonal in plan and constructed of less durable materials, particularly turf and timber. By the middle of the first century CE, however, permanent fortresses of the typical playing-card shape were the standard, as, for example, the stone fort at Hofheim. Stone as a building material became predominant in the late first and second centuries, especially following the civil wars of 69 CE. During the process of consolidating the empire under Hadrian, permanent boundaries were constructed, the most famous of which is Hadrian's Wall, which extends the entire width of Britannia at its narrowest point between the Solway in the west and the Tyne in the east (Fig. 8). These borders brought with them the development of new forts and other types of military structures such as milecastles and watchtowers.

In proximity to the camps often developed civilian settlements called *canabae* for legionary bases or *vici* for auxiliary forts. The best understood of the *canabae* in the western provinces are *Isca Silurum* (Caerleon), *Noviomagus* (Nijmegen), and *Bonna* (Bonn), and the *vicus* at

Western Roman Provinces, Archaeology of the, Fig. 8 Hadrian's Wall (©S. McGowen)

Vindolanda has been well excavated. Though it is not clear whether these settlements served agricultural purposes, certainly various types of manufacturing, such as bronze working and terracotta production for both pottery and tile, occurred in most. Some even had features resembling fora, the precise function of which is uncertain.

Current Archaeological Trends

Along with numerous subsidiary regional journals, there are four main academic journals for archaeological material from Western Europe. *Britannia*, sponsored by the Society for the Promotion of Roman Studies, is the primary publication for the province of Britannia. *La Revue Archeologique*, published by the Société Archéologique d'Alep, is the main venue for archaeological material from the French provinces, although its purview extends to material from much of the Mediterranean and even into Central Asia. *Bonner Jahrbücher*, published through the Rheinisches Landesmuseum Bonn and the LVR-Amt für Bodendenkmalpflege im Rheinland, has as its focus primarily material from the Rhineland areas, but it also includes articles on all aspects of archaeology in Europe. Finally, the primary resource for archaeological activity in Spain is Archivo Español de Arqueologia, which is sponsored by Archivo Español de Arte y Arqueología.

Many interdisciplinary and international conferences have either been instituted or have developed dramatically on particular topics relevant to the western provinces. For example, the International Congress of Roman Frontier Studies, also known as Limeskongress, which was first held in 1949, will conduct the twenty-first meeting in September 2012 in Ruse, Bulgaria. Similarly, the International Colloquium on Roman Provincial Art is held biennially. This conference series, which began in the 1980s, had as its original focus the countries of Western Europe, but in 2007 it was opened to the eastern provinces as well. In addition to the papers presented at these conferences, they have also generated monographs important to the study of this region.

The archaeology of the western provinces has also seen dramatic growth in the availability of online resources. For instance, an international research project conducted from 2004 to 2007 and funded by the European Commission, General Directorate for Education and Culture within the framework of the sponsorship program, "Culture 2000," has produced a website detailing the archaeology of all the western Roman provinces (http://www2.rgzm.de/transformation). Pottery from the region is well catalogued and analyzed as part of the Potsherd: Atlas of Roman Pottery project (http://potsherd.net). Similarly, much of the Gallo-Roman sculpture has been digitized and catalogued by the Centre Camille Jullian (http://nesp.mmsh.univ-aix.fr/). This project is part of a larger effort to update the printed catalogues of Gallo-Roman sculpture, compiled in the late nineteenth and early twentieth centuries by Émile Espérandieu. Three volumes in this new series, under the title *Nouvel Espérandieu*, have already been published with more volumes currently under production.

Wheats: Origins and Development

Dorian Q. Fuller and Leilani Lucas
Institute of Archaeology, University College London, London, UK

Basic Species Information

Wheat is one of the world's most widely grown crops today. Together with its typical companion cereal and barley, wheat was the staple cereal crop of several early civilizations extending from the Indus, to Mesopotamia, to ancient Egypt, and throughout the Mediterranean. However, the term, wheat, is to some degree a misnomer, as it is not a single crop species but a complex of several related crop species that belong to the genus *Triticum* (i.e., *Triticum* spp.). The various species within this genus derive from hybridizations and multiple domestications, including the hybridization of wheat and the closely related goat-faced grasses (*Aegilops* spp.), and from post-domestication evolutionary advances, such as the evolution of free-threshing spikelets.

The first major spectrum of variation in the wheats is at the ploidy level (i.e., variation in the number of sets of chromosomes). Figure 1 illustrates the approximate maximal extent of crops of each ploidy level based on traditional agriculture and archaeobotanical data. In current taxonomy, each ploidy level is recognized as a separate species, with traditional cultivar groups and both wild and domesticated forms grouped as subspecies. In this system, there are three main biological species, *Triticum monococcum* (diploid), *T. turgidum* (all tetraploids), and *T. aestivum* (all hexaploids). For example, wild emmer

Wheats: Origins and Development, Fig. 1 Geographical distributions of wild wheats (*Triticum* spp.), with different lines representing the approximate limits of the spread of wheats of different ploidy level. Representative archaeological evidence for the earliest wave of wheat dispersals is indicated by broad time horizons

wheat should be *T. turgidum* ssp. *dicoccoides;* domesticated emmer wheat, *T. turgidum* ssp. *dicoccum*; and free-threshing hard wheat, *T. turgidum* ssp. *durum*. However, in practice most archaeobotanists continue to use a somewhat more traditional binomial system in which hulled (e.g., *Triticum dicoccum*) and free-threshing varieties (e.g., *T. durum*) and wild varieties (e.g., *Triticum dicoccoides* and *T. boeticum* instead of *T. monococcum* ssp. *boeticum*) are considered distinct species (see Zohary et al. 2012, for a comparison of these systems). This classification system makes more explicit the communication of archaeological findings and makes available valuable data-table space. These variations in wheats are culturally significant, as each species has a different potential in terms of agricultural ecology and food use. Further, this classification scheme distinguishes between the wheats based on the archaeological implications, including evidence suggestive of agricultural and food processing practices, specifically whether the grains are from a wild or domesticated and hulled or free-threshing variety.

Major Domestication Traits

The domesticated varieties can be separated based on their response to threshing, specifically, whether the product of threshing is spikelets or grains. In hulled varieties, including *T. monococcum*, *T. turgidum* ssp. *dicoccum*, and *T. aestivum* ssp. *spelta* (spelt wheat), the grains are tightly encased in the glumes that do not release the grains during threshing. This is in opposition to the free-threshing varieties, including tetraploid durum-type (i.e., *T. turgidum* ssp. *durum*) and hexaploid bread wheats, which are not enclosed tightly and release easily during threshing with the result a naked kernel. The archaeological implication is related to the end product of threshing (i.e., spikelet or grains) and how the crop is stored and distributed thereafter. The hulled varieties can be stored for longer periods because they are protected by the glumes. They are distributed as spikelets and will need to be freed from the glume before further processing, unlike the free-threshing varieties which are ready to be milled after winnowing and sieving (Zohary et al. 2012).

Timing and Tracking Domestication

Although all of the wild wheat varieties have a restricted distribution in southwest Asia, mainly in the "Fertile Crescent" and Anatolia (Fig. 1), wheats are likely to derive from several domestication events across this geographical range. This issue has been the focus of debate in recent years between scholars who favor a single focus of all Near Eastern agricultural origins in a restricted part of southeastern Turkey (e.g., Abbo et al. 2010, 2013), where wild wheats, barley, lentil, and pea overlap with wild chickpea, and those who favor the archaeobotanical evidence for a gradual domestication process of diverse sets of crops over a very wide geographical range of the Fertile Crescent (e.g., Fuller et al. 2012; Asouti and Fuller 2012).

While there are debates on the pace and geographic distributions of domestication, all scholars accept that there were at least three domestications of wild wheats, from wild einkorn (*T. boeticum*), wild emmer (*T. dicoccoides*), and wild Timopheev's wheat (*T. araraticum*). However, archaeobotanical evidence is suggestive of additional domesticated forms of wheat that indicate additional domestications, such as two-grained einkorn and a recently recognized "emmer" type, or striate emmeroid. The former may have been domesticated from *T. urartu* and the latter an early Timopheev's wheat (*T. timopheevii* domesticated from *T. araraticum*), although confirmation supported by genetic evidence is not yet available. In addition to these four or five morphologically distinct domestication events, growing genetic data suggest that there were multiple regions of early cultivation, certainly for emmer wheat (Fuller et al. 2012).

The existence of now extinct domesticated morphotypes highlights the incompleteness of the presence of modern landraces for representing the original genetic diversity of early cultivars. Figure 2 represents the current understanding of domestication processes of wheat, specifically the selection for non-shattering rachises, which results in domesticated glume wheats. In each case, this was also accompanied by a gradual

Wheats: Origins and Development, Fig. 2 Diagram representing the current understanding of the selection for non-shattering rachises that resulted in the glume wheats of *Triticum* spp.

Wheats: Origins and Development, Fig. 3 Diagram representing the post-domestication improvement of wheat through the evolution of free-threshing forms and retro-evolution of hexaploid glume wheats

increase in grain size over the course of the Pre-Pottery Neolithic in southwest Asia, i.e., between c. 9500 BCE and 6000 BCE, after which changes in grain sizes in glume wheats were negligible. In the case of two-grained einkorn (probably from wild *T. urartu* but plausibly *T. boeticum* ssp. *thauodar*), domestication appears to have been focused on the upper Euphrates region in Syria (Willcox et al. 2008) and it quickly spread to Cyprus shortly after the first signs of domestication in this region (Lucas et al. 2012). In the case of one-grained einkorn (*T. monococcum*), an early focus might have been further to the northwest in Syria and/or in southeastern Turkey. In the case of emmer wheat, the current evidence suggests two foci, one in southeastern Turkey and the other in the southern Levant (Jordan Valley and/or Damascus basin). In the case of striate emmeroid (Possibly form *T. araraticum*), a wheat which was to become an important Neolithic crop at Anatolian sites, such as Çatalhöyük, and in Neolithic and Bronze Age Europe (Kohler-Schneider 2003), as well as spread to Turkmenistan, a domestication somewhere in eastern Anatolia seems most likely. Free-threshing (or naked) wheat evolved early in the history of wheat cultivation, as a form of secondary ennoblement. This took place at least once from tetraploid emmer and at least once by hybridization to produce hexaploid bread wheats (Fig. 3). These free-threshing wheats have the advantage of requiring less crop-processing stages and labor, although they may be more prone to spoilage in storage. Forms of hexaploid glume wheat, such as spelt (*T. spelta*), evolved from free-threshing hexaploid wheats (Fig. 3), presumably in part as better adaptation to primitive storage conditions and cooler climates. Spelt wheat became widespread in Europe from the Middle or Late Bronze Age.

Wheats were an essential part of the founder crop package that dispersed from the "Fertile Crescent" (Fig. 1) westwards through Neolithic Europe, starting about 7000 BCE and reaching the British Isles just after 4000 BCE. It similarly spread rapidly eastward to the Indus Valley and Turkmenistan, where there is evidence of wheat by 6000 BCE. The dispersal into Egypt and up the Nile is later, while the spread of wheat in monsoonal India or to southern Arabia took place after 3000 BCE. The first wheats in southern India appear to date more recently than 2000 BCE. In China, the earliest directly dated wheat is around 2400 BCE and a fair number of sites have evidence of wheats at c. 2000 BCE (Flad et al. 2010). Different species of wheats, or sets of wheats, spread along these different trajectories; each

was suited to varied ecologies and different culinary traditions. In general, it was glume wheats that were most important early on, e.g., emmer wheat in ancient Egypt or Yemen and einkorn wheats in Neolithic central Europe (Colledge and Conolly 2007). In the eastward spread of free-threshing wheats, mainly hexaploids were prominent in the case of the Indus Valley. Based on the current evidence, hexaploid free-threshing wheat was the only species that was adopted in eastern Asia (Boivin et al. 2012).

Identification of the different domesticated varieties of wheats in the archaeological record can be distinguished by comparison of grain morphology and size, spikelet fork morphology, and with the free-threshing wheats, the rachis segments (for additional criteria on identification, refer to Jacomet 2006; Zohary et al. 2012). For einkorn wheat, the two domesticated varieties can be distinguished by grain morphology. Grains of the one-grained variety are "spindle-shaped," whereas the grains of the two-grained variety are straight and flat, as opposed to curved when viewed ventrally. The spikelet forks of einkorn wheat can be distinguished in abaxial view as the angle between the lower parts of the two primary keels (glumes) is relatively small and measures less than 90°, as opposed to the angle observed in emmer wheat which is larger than einkorn and measures greater than 90°. When viewed in cross section, the shape of the lower part of the glume base is rounded and almost rectangular as opposed to clearly rectangular as in the glume bases of emmer wheat. When viewed laterally, the internode is broad in relation to the width of the spikelet. The grains of emmer wheat are generally more rounded at the apical end when viewed dorsally and are tapered at the embryo ends. In lateral view, the grains have a flat or slightly concave ventral surface with the highest point above the embryo on the rounded dorsal side. There is considerable overlap in the morphology of the free-threshing wheat grain varieties, but generally the grains of naked wheat, when viewed dorsally, are slender to round, with the apical and embryo ends bluntly rounded. The morphology in cross section is generally symmetrically rounded as is the dorsal ridge when viewed laterally. The rachis remains of the free-threshing wheats (tetraploid versus hexaploid) can be distinguished based on the glume base remnants and cross section. For the tetraploid durum-types, the glume remnants persist with two protrusions on the top of the rachis segment. In cross-section the segment tends to be rounded and thick. In hexaploid wheats the glumes bases are entirely torn off leaving concave scars. In cross-section the hexaploid rachis is thin with sharp edges.

Wheeler, Mortimer

Gabrielle Sexton
College of Humanities, Arts and Social Sciences, Flinders University, Adelaide, SA, Australia

Basic Biographical Information

Sir Robert Eric Mortimer Wheeler, commonly known as Mortimer, was born in Scotland in 1890, to a father who was a journalist (Piggott 1977: 623). He attended Bradford Grammar School, and went on to complete a degree in archaeology at University College in London. In 1913, Mortimer Wheeler began the studies that led to his postwar doctoral research on Roman pottery in the Rhineland (Piggott 1977: 624). After completing a Masters degree at the University of London in 1912, Wheeler was awarded a Franks Archaeological Studentship, which allowed him to undertake doctoral research in the Rhineland (Wheeler 1958: 31–32). However, this was temporarily delayed by the First World War, in which he served, and from which he emerged as a Major with a Military Cross. After serving in World War I, he conducted excavations of Roman sites in Essex. Mortimer Wheeler was awarded a Ph.D. from the University of London in 1920. The identity of his doctoral supervisor is unknown, and the topic of his thesis seemed to hold little importance to him, especially in later years, when he stated in his autobiography that "nothing need be said" of the trip (Wheeler 1958: 32).

From 1920 to 1926, Mortimer Wheeler held the joint positions of Keepership of Archaeology in the National Museum of Wales and Lecturer in Archaeology at the University of Cardiff (Piggott 1977: 626). In 1924, he became Director of the National Museum of Wales (Wheeler 1958: 58). In 1926, he moved to London, where he obtained the post of Keeper of the London Museum, which he held until 1946 (Piggott 1977: 628). From 1948 to 1955, Mortimer Wheeler was Chair of the Archaeology of the Roman Provinces at the University of London (Piggott 1977: 638).

Mortimer Wheeler's primary research interest was Roman archaeology. He undertook excavations of Roman sites in Wales, from 1920 to 1926, and in Hertfordshire, from 1930 to 1933, where he unearthed a pre-Roman settlement (Wheeler 1958: 56, 88). Wheeler undertook a second period of military service during the Second World War and rose to the rank of Brigadier (Piggott 1977: 635). During this war, he took advantage of the discipline of his fellow soldiers to enlist their help in recording potential sites.

In 1941, Mortimer Wheeler was elected as a Fellow of the British Academy (Piggott 1977: 638). Two years later, he was appointed Director-General of Archaeology in India (Wheeler 1958: 162), and in 1950, he was also appointed as the Archaeological Adviser to Pakistan (Piggott 1977: 637). He was the elected President of the Society of Antiquaries in London from 1954 to 1959 (Piggott 1977: 640). In 1952, he received a knighthood from Queen Elizabeth II in recognition of his contributions to archaeology. He was a steadfast and active archaeologist up to his death in July 1976.

Major Accomplishments

The majority of Wheeler's work centered around Roman sites in Wales, forming the subject of his

first seven published works, but his later work was in India, subsequent to him being appointed the head of a museum in Pakistan. However, his major contribution to archaeology lies in contributing to significant improvements in archaeological methods, especially through the stratigraphic trenching method that developed with Kathleen Kenyon (Davis 2008); in his publications for the general public (Wheeler 1958, 1961); and in his role as the public face of archaeology in the early years of television during the 1950s.

Wheeler was strongly influenced by the work of his contemporaries, General Pitt-Rivers and Flinders Petrie, who were also committed to rigorous excavation and recording methods. Wheeler was deeply concerned with the practice of excavation, and in ensuring that this was done correctly and methodically, as opposed to the rather ad hoc and frequently destructive excavation methods employed up to that time. The accurate and careful study of different cultures was important in his work, especially in terms of the significance of stratigraphy. Wheeler believed that the true value of excavation lay in the recovery of primary information from sources that were not documents (Piggott 1977: 625).

Wheeler made a significant contribution to the development of archaeological excavation methods. His respect for each site, and desire to keep excavation damage to a minimum, is a consistent theme throughout his publications. He was also one of the first archaeologists to recognize the importance of stratigraphy, and to use it to date sites and determine the number of cultures in a particular area (Wheeler 1961: 56–59). He argued vigorously that careful excavation and analysis, and continuous use of stratigraphical references, were key to determining information about early cultures.

Mortimer Wheeler's final research project culminated in his book *Civilizations of the Indus Valley and Beyond*, written in 1961 and revised in 1966. By this time, his focus on methodical excavation had led him to develop the grid method of excavation, in collaboration with Kathleen Kenyon, based upon the premise that the easiest and most systematic method to survey a site is by using squares (Wheeler 1961: 83). Throughout his book *The Indus Civilization*, Wheeler reiterated the importance of correctly observing the location of artifacts and the systematic and recorded excavation of sites to allow for meaningful re-excavation (Wheeler 1962).

Sir Mortimer Wheeler made a major contribution to public education in archaeology in Britain. During the 1950s, he became one of the main public faces of archaeology when he made regular appearances in the BBC series *Animal, Vegetable or Mineral* (Brass 1955) in an effort to place archaeology in the public psyche. As a result, Wheeler was voted Television Personality of the Year for 1955 (Brass 1955). During this period, Wheeler continued to publish work about his excavations, in particular focusing on the importance of stratigraphy, and the influential grid method of excavation that he developed in collaboration with Kathleen Kenyon (Wheeler 1961: 83).

Throughout his life, Sir Mortimer Wheeler worked assiduously to achieve better standards in archaeological method and analysis, and to create greater public awareness of the discipline. He accomplished both aims. His methods of excavation became the standard and the public developed a growing interest in archaeology. He published a plethora of books and papers over his lifetime and left a far-reaching legacy that revolutionized the archaeology of his era and which still has impact today.

White, J. Peter

James O'Connell
Department of Anthropology, University of Utah, Salt Lake City, UT, USA

Basic Biographical Information

John Peter White is an Australian archaeologist and editor. He was born in New Zealand (1937), raised in Australia, and educated at the University of Melbourne (BA 1961, History), University of Cambridge (BA 1963, MA 1967, Archaeology and Anthropology), and the Australian National University (PhD 1968, Prehistory). He was awarded British Commonwealth Undergraduate and Graduate Fellowships (1956–1959, 1961–1963, 1964–1967) and a postdoctoral Harkness Fellowship (1970–1971). He held appointments at Melbourne (Tutor, 1960–1961), the Australian Museum (Assistant Curator, 1967–1970), and the University of California at Berkeley (Postdoctoral Fellow, 1970–1971) before joining the Department of Anthropology at the University of Sydney in 1971, where he remained until 1992 (Lecturer 1971–1974, Senior Lecturer 1974–1978, Reader 1978–1992). Successive University reorganizations shifted his appointment as Reader to the School of Archaeology, Classics and Ancient History (1992–2000), the School of Philosophy, Gender, History and Ancient World Studies (2000–2002), and the School of Philosophical and Historical Inquiry (2002), the post from which he retired in 2003. While employed at Sydney, he held visiting appointments at UC Berkeley (1976), ANU (1977, 1979, 1997–1999), and the Universities of Arizona (1979), Auckland (1981), and Papua New Guinea (1984). Since 2003, he has been Adjunct Professor of Archaeology at the University of New England (Armidale). He served as Editor of the journals *Mankind* (1974–1978) and *Archaeology in Oceania* (1980–present [2012]). He has been appointed to numerous editorial boards and advisory panels and has been honored by election to the Australian Academy of the Humanities (1985) and by collected papers in a special issue of *Australian Archaeology* (Specht et al. 2003).

Major Accomplishments

White has published or edited more than 130 books, journal articles, book chapters, and notes on a wide range of topics, within Australia and beyond, including regional prehistory, ethnoarchaeology, lithic, ceramic, faunal and raw material source analysis, economic change, artifact "style" and society, radiocarbon dating, rock art, and the history and politics of archaeology. He pioneered new approaches to lithic analysis through direct observation of stone tool manufacture, use, and discard in the New Guinea Highlands, forcing a shift away from standard culture historical taxonomies based on overall artifact form toward the definition of functional tool categories based on working edge attributes as units of analysis (White 1969). His comparative analysis of Australian versus European lithics drew attention to the limits of conventional inferences about connections between tool form and makers' cognitive and behavioral capabilities (White 1977). His archaeological fieldwork produced the first evidence for Pleistocene human occupation of the New Guinea Highlands (White et al. 1970) and (in collaboration with other members of the Lapita Homelands Project) yielded similarly early dates for colonization of the Bismarck Archipelago (Allen et al. 1988). His several syntheses and edited volumes on the prehistory of Sahul (Pleistocene Australia-New Guinea) have

drawn global scholarly attention to the similarities and differences that distinguish this region from other parts of the world, particularly with respect to time of arrival, the identities of founding populations, and their impact on regional biota, including megafaunal extinctions and the development of agriculture (e.g., Denham and White 2007; White with O'Connell 1982). As a public intellectual, he advocated scientific rigor in opposition to unsupported speculation about the human past (White 1975). As editor, he made *Archaeology in Oceania* for three decades the key outlet for regional research on the human material record.

Wilkinson, Tony James

Charles French
Department of Archaeology, University of Cambridge, Cambridge, UK

Tony Wilkinson is the foremost authority in geoarchaeologically grounded landscape archaeology in the Near East. I first met Tony at Francis Pryor's major excavations at Fengate, Peterborough, England, in June 1975 (Fig. 1). Tony was a great digger with an eye for stratigraphic detail, setting him apart from most of the Fengate crew, and an easy ability to impart his skills in stratigraphic reckoning to those for whom it was more challenging. This talent remained with him and enabled his students and field assistants to learn quickly under his guidance. Also at this time Tony introduced me to the delights of various 1960s and 1970s Motown and blues artists through second-hand record stalls in Peterborough market. This love of music was his second and unsung talent that he much enjoyed, especially when he was living in Lincoln and Chicago. Indeed, Tony played a mean harmonica.

Tony was born in August, 1948, and grew up in Essex before going to London read Geography at Birkbeck College (1966–1969). He then crossed "the pond" to McMaster University in Hamilton, Canada, where he continued his training as geographer (1970–1972). Here his research focused upon the hydrology of overland flow in the Canadian High Arctic. He then returned to England and started working as a circuit digger. After Fengate, Tony was taken on by the Central Unit, essentially a "flying squad" of hard drinking excavators working for the Chief Inspector of Ancient Monuments for England and Wales, Geoff Wainwright. He survived some very severe winters working with the Central Unit at sites such as Shaugh Moor on Dartmoor, before taking on his own English Heritage funded project with Peter Murphy: The Hullbridge Survey (1982–1988). This involved intensive survey of the coastal and river estuarine landscapes of the Rivers Stour, Colne, Blackwater, Crouch, and Roach as well

Wilkinson, Tony James, Fig. 1 Tony Wilkinson at the Iron Age and Romano-British settlement site of Cat's Water Fengate, Peterborough, Cambridgeshire, in July 1975

as the north shore of the Thames estuary in Essex (Wilkinson and Murphy 1995) and excavations of the drowned Neolithic site at The Stumble (Wilkinson et al. 2012). This is where Tony developed his particular combination of archaeological survey and geomorphological skills that he has employed to great effect in all his subsequent work in the much drier climates of the Near East, in countries such as Iraq, Oman, Yemen, Saudi Arabia, Syria, Turkey, and Iran over a period of more than 30 years.

By the time that Tony became a Research Associate and Associate Professor at the Oriental Institute in Chicago (1992–2004), he had already undertaken extensive fieldwork in the Near East and had been the Assistant Director of the British Archaeological Expedition to Iraq in Baghdad between 1989 and 1992. I again worked with Tony in the Dhamar region of the highlands of Yemen in the late 1990s where new field survey revealed hundreds of new prehistoric sites, many of which were buried by substantial hillwash eroded deposits. This research led him to suggest that the combined influences of human impact and underlying climate change acted as the twin drivers of major landscape change in semi-arid landscapes such as these (Wilkinson 2003a, 2005a).

This extensive and ground-breaking survey work in the Near East and southern Arabia was brought together in the publication of his book on the *Archaeological Landscapes of the Near East* (Wilkinson 2003b). For this Tony received the prestigious Book Prize from the Society for American Archaeology in 2004 and also the Wiseman Book Award of the Archaeological Institute of America in 2005. This book establishes a new framework for understanding the settlement structure and evolving landscape of the ancient Near East set against the backdrop of contemporary environmental, social, and economic conditions.

At this same time Tony used his unique combination of geomorphology and settlement distribution type of field survey work to inform modeling approaches to investigating the organization of irrigated landscapes and site territories in southern Arabia and Syria (Wilkinson 2005b; Wilkinson et al. 2007). This brought his geographer's background to bear on archaeological site distribution data and led to the award of a large National Science Foundation grant (2002–2005) for "Settlement systems within a dynamic environment and economy: contrasting northern and southern Mesopotamian city regions."

Tony then re-emigrated back across the Atlantic with his wife Eleonor to take up a Lectureship in the Department of Archaeology at the University of Edinburgh, briefly in 2004–2006, before moving on to a new Professorship position at the University of Durham in 2006. There his most

recent research project is the Fragile Crescent Project (2008–2012) funded by the Arts and Humanities Research Council, which aimed to advance our understanding of the settlement landscapes of Upper Mesopotamia and the northern Levant (Galiatsatos et al. 2009). This project has brought together data drawn from archaeological surveys and satellite imagery into one analytical framework to provide a data source to rival that available for southern Mesopotamia. Projects such as this must be seen a significant culmination to most of a lifetime of archaeological and geoarchaeological survey work in the Mesopotamian region and beyond. In the current troubled times, this study is even more valuable and his colleagues are currently in discussion with UNESCO regarding ways in which the project's database may contribute to the protection and management of Syria's endangered heritage.

In honor of Tony's lifetime achievements to archaeological landscape survey, he was aptly made a Fellow of the British Academy in 2008 and awarded the John Coles Medal for Landscape Archaeology in 2009, also by the British Academy.

On Christmas day 2014 Tony passed away after a lengthy battle with cancer. In typical style, he had continued working on his AHRC Fragile Crescent publication to the very last (Bradbury and Philips 2011; Cunliffe 2012). His final send-off in the parish church in his home village of Brancepeth in County Durham on January 26, 2015, was a fine celebration of a life very well lived. Tony was a fine man, friend, and scholar.

Willems, Willem J.H.

Monique H. van den Dries
Faculty of Archaeology, University of Leiden, Leiden, The Netherlands

Basic Biographical Information

Professor Dr. Willem J.H. Willems (1950–2014) was one of the most prominent Dutch archaeologists. He steered three main national organizations and played a major role in the restructuring of the archaeological heritage management system in

the Netherlands. He was also very active in the international arena of heritage management and produced an impressive list of academic publications. Without doubt, Willems also took the lead in committee and board participations, in presidencies, in academic professorships, in network size, and in air miles. During his long and impressive career of nearly 40 years, his professional passion was threefold: Roman archaeology, archaeological heritage management, and international collaboration.

After his academic training in Roman archaeology and anthropology at the University of Amsterdam and in anthropology at the University of Michigan (USA), he started his professional career in 1979 as the provincial archaeologist of Limburg, the province in the southern part of the Netherlands where he was born. He continued in Roman archaeology with a PhD dissertation (1986, cum *laude*) entitled *Romans and Batavians* and with numerous articles and monographs. Both in the Netherlands and internationally, he was considered as one of the leading Roman specialists. In 1985, he became project manager for the Roman period at the State Service for Archaeology (ROB, now *Rijksdienst Cultureel Erfgoed*, www.cultureelerfgoed.nl) in Amersfoort, and 2 years later, he also became professor of Roman archaeology at the University of Leiden.

Major Accomplishments

Inspired by the CRM developments he had witnessed in the USA, he not only developed his taste for excavating Roman sites but also grabbed the challenges to preserve them, as well as some of the other types of sites. Heritage management even became his main concern when in 1989 he became the director of the ROB. As such, he also developed an interest in the social role of archaeology, especially the relation between science and society. He could also bring these interests into practice on an international scale, when in the early 1990s he was part of a committee of experts from the Council of Europe that drafted the Convention for the Protection of the Archaeological Heritage (also known as the Malta convention). His approach and view on heritage management and academic quality was probably ultimately challenged when he was asked (in 1999) to become the director quality management for archaeology at the Ministry of Education, Culture and Science. His main task was to direct the adaptation of the Dutch archaeological heritage management system to the implementation of the principles of the Malta Convention, a complex and delicate process. He however accomplished that the future commercially based heritage management system would be accompanied by quality assurance measures. Subsequently, he vigorously chaired the committee that successfully developed the Dutch Quality Standard. After its completion, he was appointed as Inspector General for Archaeology (2001) and could start to mold the State Inspectorate for Archaeology (now Heritage Inspectorate, www.erfgoedinspectie.nl). It had to monitor in practice the quality of the archaeological work that was undertaken under the new regime and in a commercial setting. In 2006, he exchanged this position for one in Leiden, where he got a second professorship at the university, for the chair of archaeological heritage management. At the same time, he became the Dean of the Faculty of Archaeology (till 2013). He established a heritage management research group with PhD candidates from all over the world and started the first master's degree specialization in heritage management with a global orientation. He has also published extensively on this subject (Fig. 1).

His wide horizons and endless affiliation with archaeological matters are reflected in the huge number of Dutch committees, executive boards, and editorial boards he participated in (such as the Dutch Archaeology Foundation, the RAAP Foundation, RING Foundation, Central Committee of Experts for Archaeology – CCvD, the Van Es Award Committee, ICOMOS Netherlands, the Centre for International Heritage Activities (CIE)). On the international level, the list is even longer. Ever since his studies in the USA, he remained intensely involved in the international arena, for instance, through his membership of the Society for American Archaeology and of the Register of Professional Archaeologists. In Europe, he was the vice president for Europe of

Willems, Willem J.H., Fig. 1 Willems opening a seminar of the Inspectorate, March 2003. (Photo: State Inspectorate for Cultural Heritage)

the ICOMOS Committee for Archaeological Heritage Management, the founding president of the Europae Archaeologiae Consilium, and the president of the European Association of Archaeologists (1998–2003). After that, he chaired the latter's Archaeological Heritage Prize Committee. In 2009, he was elected copresident (with Douglas C. Comer) of ICAHM and in 2010 Willems was elected as 1 of the 12 members of the European Union's academic committee Joint Programming Initiative on Cultural Heritage and Global Change. On top of this all, he occasionally evaluated nominations for World Heritage Sites (Fig. 2).

For many of his achievements, Willems was honored with prizes and honorary memberships. To mention just three of the most prestigious ones, in 2004, he was the Recipient of the Rheinlandtaler, which is awarded by the Landschaftsverband Nordrhein-Westfalen in Bonn, and in 2010, he received the Special Achievement Award of the Register of Professional Archaeologist's for his efforts in the Malta Convention and in heritage management in Europe and internationally. In April 2015, he received posthumously the Presidential Recognition Award of the Society of American Archaeologists.

Willems' achievements are celebrated by 40 of his friends and colleagues in Fernweh – Crossing borders and connecting people in archaeological heritage management. Essays in honour of prof. Willem J.H. Willems (2015).

Willendorf II: Geography and Culture

Philip R. Nigst
Department of Archaeology and Anthropology, University of Cambridge, Cambridge, UK
Department of Human Evolution, Max Planck Institute for Evolutionary Anthropology, Leipzig, Germany

Introduction and Definition

Willendorf II, a site originally excavated about a century ago, is one of the more important European Upper Paleolithic sites in part for the discovery of the famous Venus I figurine but also for the data it can provide on the earliest Aurignacian. Excavations at Willendorf II have yielded a long loess-paleosol succession with a rather high paleoclimatic resolution. Embedded in this sequence are ten archaeological horizons separated by sterile loess deposits. The archaeological horizons are attributed to an unspecified Early Upper Paleolithic, the Aurignacian, and the Gravettian. Radiocarbon dates on abundant high-quality conifer charcoal provides a reliable chronological framework. Willendorf II is one of the rare sites to offer a good chronostratigraphic framework for the period between 45,000 and 25,000 ^{14}C BP in Central Europe.

The site Willendorf II is located about 80 km west of Vienna, Austria, in the Danube valley. This part of the Danube valley is called Wachau, which belongs to the geological unit of the Paleozoic Bohemian Massif. The Danube valley cuts deep into this massif and is characterized by rather steep and sometimes cliffy slopes. In this narrow part of the valley on the loess covered left/west bank of the Danube, a cluster of 8 Paleolithic sites is known consisting of Willendorf I, Willendorf I-Nord, and Willendorf II to VII. The deposits of the site Willendorf II lie on top of a lower terrace of the Danube. The archaeological horizons are found in the upper half of about 20-m-thick loess, loess-like, and loamy deposits.

Key Issues/Current Debates/Future Directions/Examples

Excavation History

The first mention of Willendorf II as a Paleolithic site goes back to the second half of the nineteenth century. Later, in 1907, during more extensive work at the nearby site of Willendorf I, M. Much excavated for a few days at Willendorf II. Also in 1907 the construction of the railroad in the Danube valley started. The associated earthworks resulted in a whole series of new sites in the Danube valley, among them Willendorf I-Nord and Willendorf III to VII. From May to July 1908, H. Obermaier and J. Bayer (Naturhistorisches Museum, Vienna) visited the railway construction sites on a daily basis and documented the archaeological occurrences. On 29 July 1908 the first scientific excavation at Willendorf II was started. J. Szombathy (Naturhistorisches Museum, Vienna) directed the excavation, while Obermaier and Bayer directed the work in Szobathy's absence. During that first excavation most of the sequence was exposed. Archaeological horizons (AH) 3–9 were identified. The most important and obviously most famous object ever found at Willendorf II is the *Venus I* figurine, which was found on the 7th of August 1908. The work in the course of this first excavation campaign at the site lasted until September 1908 (Felgenahuer 1959).

Szombathy directed a second excavation from 19 April to 5 July 1909; Bayer was responsible for site supervision. During this excavation, the lower part of the sequence containing AHs 1 and 2 was exposed. Also, more surface in AH 4–9 was excavated.

In 1912, Szombathy conducted fieldwork east of the railway tracks in the area of the old brickyard to explore the potential for future excavations in this area of the site. From 1913 onward, Bayer continued the fieldwork on a small scale. After a break of some years, Bayer continued his excavations in 1926 and 1927. During these excavation campaigns the *Venus II* and *Venus III* figurines were discovered.

In 1955, Willendorf II was re-excavated by F. Felgenhauer (1959). Besides a 25-m-long test

trench, Felgenhauer's team excavated a surface of approximately 10 × 20 m in the north of the earlier excavations. During this work, geological work was conducted by F. Brandtner (Felgenhauer 1959). After Felgenhauer's excavation finished, severe destruction was done to the site through different agents.

In 1981, P. Haesaerts (Royal Belgian Institute of Natural Sciences, Brussels, Belgium) started his work in Willendorf II. His team cleaned a small section and took a number of samples for radiocarbon dating, sedimentological analysis, and paleoclimatic/paleoenvironmental reconstruction (Haesaerts 1990). About 10 years later, in 1993, P. Haesaerts, F. Damblon (both Royal Belgian Institute of Natural Sciences), and G. Trnka (University of Vienna) started a collaborative research program on Willendorf II to enlarge the 1981 section and to collect more well-provenienced samples for dating and reconstruction of the paleoenvironment. The results of this work form the basic description of the sequence up to now (Haesaerts et al. 1996; see also Nigst and Haesaerts 2012).

Since 2006, an interdisciplinary team is conducting new fieldwork at the site (Nigst et al. 2008a, b). The goals of this work are to get a better understanding of the site formation processes, to establish a more reliable chronostratigraphic framework for the archaeology at Willendorf II, and to reconstruct the paleoenvironment and climate. Archaeologically, the fieldwork focuses on the Aurignacian archaeological horizons three to four.

Chronostratigraphy

The stratigraphic sequence consists of six loessic and loamy bodies lying on top of a low terrace of the Danube. For the lower half of the sequence (stratigraphic units (SU) H to E), we have only limited information from the fieldwork and geological studies during the early excavations (Brandtner, in Felgenhauer 1959). For the upper part of the sequence (SU D to A), much more information is available based on the work of Haesaerts (Haesaerts 1990; Haesaerts et al. 1996; Nigst and Haesaerts 2012).

The base of the sequence (see Fig. 1) is formed by Danube gravels (SU H), followed by a pale yellowish loess (SU G), a reddish brown partly reworked paleosol (SU F), and a unit of pale yellowish loess (SU E). No information is available on the age and chronostratigraphic correlation of these lower units.

SUs D and C represent the Middle Pleniglacial. SU D is described as a 2.5–3.0-m-thick stony heterogeneous brownish loam (Haesaerts et al. 1996; Nigst and Haesaerts 2012). The rich mollusk assemblage preserved in SU D1 is indicative of a rather mild climatic environment with some wooded patches near the site (Frank and Rabeder 1994), and pedosedimentary characteristics evoke a rather humid climate with drier conditions at the end. This well-expressed climatic episode, probably centered around 41,500 ^{14}C BP and also recorded in a similar position at the nearby site of Schwallenbach, was named the Willendorf Interstadial (Haesaerts et al. 1996). During the 1909 excavations AH 2 was described within the SU D. Later fieldwork attempted unsuccessfully to relocate AH 2.

SU C, about 1.5–2 m thick, consists of a complex set of stratified pale yellowish sandy loesses, bleached light gray horizons, and three humiferous horizons (Haesaerts et al. 1996; Nigst and Haesaerts 2012). The lowest of the three humiferous horizons, SU C8, occurs in parts as brownish gray lenses stretched by solifluction and contains ash stripes with concentrations of charcoal. The lithic assemblage of AH 3 is reported in the old fieldwork to be associated with SU C8 (Felgenhauer 1959). This observation was verified during the 1993 fieldwork (Haesaerts et al. 1996) and the excavation since 2006 (Nigst et al. 2008a). The ^{14}C-dates from charcoal of the humiferous horizon SU C8 give an age estimation for the AH 3 of about 39,000/38,000 ^{14}C BP (Haesaerts et al. 1996; Nigst and Haesaerts 2012). This age estimation is based on the two ^{14}C dates GrA-896 and GrN-17805. The ^{14}C date GrN-11192 provided an age of about 34,100 ^{14}C BP. This charcoal sample was not subject to the same detailed sample cleaning and identification processes (for details see, e.g., Damblon et al. 1996) prior to submission to the dating laboratory

Willendorf II: Geography and Culture, Fig. 1 Willendorf II: sequence. *Left*: schematic section of the entire deposits exposed between 1908 and 1993. *Right*: stratigraphic log of the upper part of the sequence, documented in 1993 fieldwork. Abbreviations: *SU* stratigraphic unit, *AH* archaeological horizon. (Graphic: P. Haesaerts and P.R. Nigst)

as the later dates samples, and it was at the minimal carbon weight limit for conventional ^{14}C dates (Haesaerts et al. 1996). Therefore, it has to be considered as a minimum age, and the best age estimation for SU C8 (and AH 3) is about 39,000/38,000 ^{14}C BP. The second humiferous horizon (SU C4) is less developed but almost in situ. AH 4 is located in SU C4. It has been described as an

Aurignacian with numerous carinated and nosed end scrapers (e.g., Hahn 1977). The associated ^{14}C-dates on charcoal (natural origin) date the SU C4 to 32,000/31,000 ^{14}C BP. The upper one of the three humiferous horizons, SU C2, is best expressed and occurs as a decimetric, dark brown layer slightly stretched by solifluction. The AH 5, assigned to the Gravellian, is located in this SU. The correlation of the AHs 3, 4, and 5 and these three distinct, dark-colored humiferous horizons has been observed by all excavators at the site (Felgenhauer 1959; Haesaerts 1990; Haesaerts et al. 1996; Nigst and Haesaerts 2012; Nigst et al. 2008a, b).

Altogether, SU C represents the upper part of the Middle Pleniglacial (between 39,000 and 26,000 ^{14}C BP) and records a complex succession of climatic episodes. While the sandy loess layers (SUs C7, C5, C3, and C1 pro parte) represent cold episodes, the bleached horizons (SUs C9, C6, and C1 pro parte) show characteristics of tundra gley indicating very cold conditions (deep frost or permafrost). The tundra gley of sub-SU C1 pro parte is most developed and occurs as a marker at the boundary between the Middle and the Late Pleniglacial (Haesaerts 1990; Haesaerts et al. 1996). Moreover, the three humiferous horizons (SUs C8, C4, and C2) containing AHs 3, 4, and 5 are related to interstadial episodes, such an interpretation being in good agreement with the pedological characteristics (Haesaerts et al. 1996) and the malacological content (Frank and Rabeder 1994). Taking into consideration the section of Schwallenbach – located roughly 4 km downstream on the left bank of the Danube – where three well-developed humiferous soils are preserved within a similar stratigraphic and chronological background, these three interstadial episodes were named Schwallenbach I (between 39,000 and 37,400 ^{14}C BP), Schwallenbach II (around 32,000 ^{14}C BP), and Schwallenbach III (around 30,500 ^{14}C BP) (Haesaerts et al. 1996).

SU B represents the Late Pleniglacial loess cover, which shows evidence of a progressive trend towards a cold and dry climate based on pedological characteristics and the malacological content (Haesaerts et al. 1996; Frank and Rabeder 1994). SU B comprises pale yellowish homogeneous loess layers (SUs B1 and B3), thin lenses of pale gray loess (SU B4), and a light brownish horizon (SU B2). The loess of SU B caps the thick tundra gley of SU C1 posterior to 28,560 ^{14}C BP overlain by Gravettian AH 6, reworked by solifluction, and dated to 26,500 and 26,100 ^{14}C BP. Gravettian AH 8 occurs in the middle part of SU B in association with an incipient humiferous horizon (SU B2). Charcoal from this horizon provided consistent ages between 25,800 and 25,230 ^{14}C BP. The in 2006 newly discovered Gravettian AH 8a is located in the middle part of SU B1. No excavations after 1955 were able to observe AH 9. SU A is formed by the thick humic horizon on top of the section and represents the recent soil.

A similar stratigraphic sequence was documented at the nearby site Schwallenbach (Haesaerts et al. 1996). Figure 2 shows the correlation of the two sites. This shows a similar stratigraphic sequence and the reproducibility of the record documented at Willendorf II at another site, a few kilometers downstream.

Archaeological Sequence

The archaeological sequence comprises ten AHs including six Gravettian (AH 5–9), two Aurignacian (AH 3 and 4), and two archaeological horizons which cultural attribution is unclear, but which in general are considered as Early Upper Paleolithic (e.g., Felgenhauer 1959; Hahn 1977; Otte 1981; Haesaerts et al. 1996; Nigst 2006; Nigst et al. 2008a; Nigst and Haesaerts 2012).

For both AH 1 and AH 2 the cultural attribution is unsecure and the exact stratigraphic position unclear. Both have been observed only during the 1909 excavation. Several authors have described AH 2's lithics as undiagnostic and attributed them to the Early Upper Paleolithic in general (Hahn 1977; Teyssandier 2003; Nigst 2006).

AH 3 is the lower of the two Aurignacian horizons and was excavated for the first time during the 1908 and 1909 fieldwork (Fig. 3). Further excavation is documented for 1955, but only in a test trench. Since 2006, the AH 3 has been excavated on a limited surface (Nigst et al. 2008a). Based on the lithic artifacts including carinated/nosed end scraper-cores, AH 3 is attributed by most scholars

Willendorf II: Geography and Culture, Fig. 2 Willendorf II and Schwallenbach: comparative sequences. Graphic symbols. *1*. loess; *2*. sandy loess; *3*. loam; *4*. humiferous horizon; *5*. to the Early Aurignacian technocomplex (e.g., Hahn 1977; Teyssandier 2003; Nigst 2006; Nigst and Haesaerts 2012).

The upper of the two Aurignacian horizons, AH 4, was first identified in 1908 and excavated in all fieldwork seasons since then. It is located in SU C4, a paleosol rich in charcoals dating to 32,000/31,000 ^{14}C BP. The assemblage consists of abundant lithics, bone/antler tools (Fig. 4), and a mollusk shell. Based on the lithics (Fig. 5) – including abundant evidence of the production of small bladelets from carinated/nosed end scraper-cores – AH 4 is attributed to the Early Aurignacian or Late Aurignacian.

Willendorf II: Geography and Culture, Fig. 3 Willendorf II-AH 3. AH 5 is documented in SU C2, which is a dark brownish humiferous horizons with charcoal concentrations and partly reworked by solifluction (Haesaerts et al. 1996). The archaeological assemblage includes – besides abundant lithics – worked bone/antler/ivory remains. The lithic assemblage includes pointed blades, end scrapers, Microgravette points, Gravette points, backed pieces, fléchettes, and burins and attributed to the Early Gravettian (Moreau 2009) or Early Pavlovian (Svoboda 1994).

The Gravettian AH 6 is located in SU B4, consisting of several thin lenses of pale gray loess. AH 6 is – like AH 8 and 7 – attributed to the Middle Gravettian or Evolved Pavlovian. AH 7 is attributed to the Middle Gravettian or Evolved Pavlovian as well. It was documented only in the early fieldwork and not observed in the very limited excavation in upper SUs during the most recent fieldwork.

The Gravettian AH 8 has been excavated since 1908 during several fieldwork opportunities (e.g., Felgenhauer 1959; Haesaerts et al. 1996; Nigst et al. 2008b). This AH in located in the SU B2, an approximately 5 cm thick continuous light brownish horizon, underlined by abundant traces of rootlets. AH 8 is either attributed to the Middle Gravettian or to the Evolved Pavlovian (e.g., Svoboda 1994).

In the course of section cleaning and stabilization of the western section in 2006, the new Gravettian AH 8a was discovered about 30 cm above SU B2 in SU B1 (Nigst et al. 2008b). In the same stratigraphic position Haesaerts et al. (1996) describe a horizon of charcoals, but only in 2006 also archaeological remains could be observed.

The Gravettian AH 9 is by far the richest of the archaeological horizons. It is attributed to the late (Upper) Gravettian or Willendorf-Kostenkian (Svoboda 1994). None of the fieldwork since 1955 could locate AH 9, as its richest parts were in the eastern part of the site partly destroyed by the railway construction and the remaining parts excavated in the early excavations. Lithic raw

materials are dominated by various cherts occurring in the close Danube gravels but also contain far-distance transported flint most probably originating from northern Moravia or southern Poland (Antl-Weiser 2008b). Among the retouched lithics are shouldered points, hence the attribution to the Willendorf-Kostenkian (e.g., Sovobda 1994). The Venus II and Venus III figurines originate from AH 9, while the famous Venus I figurine was found about 25 cm below AH 9 (see below).

The Venus Figurines of Willendorf II

In total three so-called Venus figurines have been discovered at Willendorf II. The most famous one is the Venus I figurine that was found on 7th of August 1908. The anthropomorphic figurine is about 11 cm tall and depicts an obese woman. The head does not show a face, the arms are resting on the breasts, and the feet are not shown. Originally the figurine was covered with red ochre, most of which was accidentally removed when it was washed. The raw material of the figurine is oolithic limestone that most probably originates from the Stránksá skála outcrops in southern Moravia (Antl-Weiser 2008a). Traditionally the Venus I figurine is attributed to AH 9, but reanalysis of the original documentation shows that its correct stratigraphic position is actually about 25 cm below AH 9 and associated with a horizon of charcoal (Haesaerts et al. 1996; Antl-Weiser 2008a, b). On the contrary, the Venus II and III figurines originate from AH 9.

The Venus II figurine, discovered in 1926, is made from ivory and in a very bad state of preservation, as preservation of organic finds at Willendorf II in general is not good. It was found together with mammoth bones in a pit that was dug from AH 9 down into the loess and some of the underlying AHs. The so-called Venus III is

a piece of ivory showing some traces of working; its interpretation as a Venus figurine was often questioned (Antl-Weiser 2008a, b).

Willey, Gordon Randolph

Robert W. Preucel
Department of Anthropology, Brown University, Providence, RI, USA

Basic Biographical Information

Gordon Randolph Willey is widely regarded as the preeminent Americanist. He was born in 1913 in Chariton, Iowa, but grew up in Long Beach, California. He studied at the University of Arizona under Byron Cummings where he received his bachelors and masters degrees. He pursued doctoral work at Columbia University with Duncan Strong and completed his dissertation on the Chancay Valley, Peru, in 1942. The following year, he joined the Bureau of American Ethnology at the Smithsonian Institute to work for Julian Steward in editing the *Handbook of South American Indians*. In 1950, he accepted the Bowditch Professorship in Central American Archaeology

and Ethnology at Harvard University, a position he held until 1987. Willey participated in or directed major fieldwork projects in eight different countries. In the United States, he has worked in Arizona, Georgia, Louisiana, and Florida. Outside of the United States, he has worked in Belize, Guatemala, Honduras, Mexico, Nicaragua, Panama, and Peru. He died on April 28, 2002.

Willey was honored with numerous professional awards and prizes. Among the most prestigious of these are the Viking Fund Medal for Archaeology (1953), the Order of the Quetzal of Guatemala (1968), the American Institute of Archaeology's Gold Medal (1973), the American Anthropological Association's A. V. Kidder Medal (1974), the Royal Anthropological Institute's Huxley Medal (1979), the Society for American Archaeology's Distinguished Service Award (1980), and the University of Pennsylvania Museum's Lucy Wharton Drexel prize (1981). He held honorary degrees from Cambridge University, the University of Arizona, and the University of New Mexico. He was a member of the National Academy of Sciences, the American Academy of the Arts and Sciences, the American Philosophical Society, the British Academy (corresponding member), and the Sociedad Mexicana de Antropología. He was a fellow of the Society of Antiquaries, the Royal Anthropological Institute of Great Britain and Ireland, the American Anthropological Association (President, 1961), and the Society for American Archaeology (President, 1968).

Major Accomplishments

Willey is perhaps best known for creating the field of "settlement pattern" archaeology. In the first half of the twentieth century, most archaeological research was concentrated upon excavating a few big urban centers with relatively little attention paid to the more numerous, smaller villages and hamlets. Willey's settlement pattern approach was a significant departure from this standard. He regarded the distribution of human settlements provided a natural starting point for the functional interpretation of archaeological cultures (Willey 1953). Different sites were best understood not in isolation, but rather as part of complex economic, social, and political landscapes. Because this approach required the study of the common people as well as rulers, it marked a shift to a more democratic orientation that recognized the dynamic interplay between elites and commoners. The widespread popularity of Willey's approach is due in part to the fact that it provided a workable methodology for addressing questions of social structure, demography, and subsistence patterning.

Willey devised his settlement pattern approach as part of the Virú Valley project, one of the first multidisciplinary research programs in the New World involving archaeologists, anthropologists, and human geographers. The goal of the Virú project was the reconstruction of the archaeology and ethnology of a small coastal valley in Peru. Willey's role was to record the forms, settings, and spatial relationships of the sites within the valley and to make inferences about the societies that created and inhabited them during successive cultural periods. Willey always attributed the idea of a settlement pattern approach to Julian Steward and downplayed his own contributions. But, in fact, his implementation of and modifications to this idea went far beyond what Steward had previously accomplished in his Southwestern studies. For example, Willey developed a more sophisticated community-based approach that allowed him to make inferences about changes in population size and sociopolitical organization over a period of 1,500 years.

Willey has often been characterized as the "grand synthesizer." There are good reasons for this. Willey provided the definitive synthesis of the archaeology of the Americas for his time (Willey 1966, 1971). He also synthesized the history of American anthropological archaeology from the speculative to the modern periods (Willey and Philips 1958; Willey 1968, 1988; Willey and Sabloff 1974, 1993). However, Willey also synthesized different kinds of archaeological theory. Throughout his career, he sought to bridge the "great divide" between humanist and scientific traditions. For him, the goals of archaeology are twofold, namely, to narrate the process of the human past and to explain and understand the events that comprise that past. Willey was a strong advocate of a comparative generalizing approach,

but not at the expense of a specific particularizing one. He argued that it is impossible to make meaningful comparisons unless the specifics of at least two contexts are well controlled.

Willey's influence on archaeological method and theory is considerable (Sabloff and Fash 2007). His work on settlement archaeology established a new field that is regarded as the starting point for all investigations of culture process and social change. His syntheses of New World prehistory and the history of American archaeology are major achievements and are commonly used as textbooks. His work has anticipated many of the recent trends in the last 30 years. For example, his functionalist and processualist approach was reinterpreted to become the centerpiece of the New Archaeology (Willey and Philips 1958). His writing style exhibits a critical self-consciousness favored by some post-processual archaeologists. His interest in ideology and the Mesoamerican worldview resonates strongly with new developments in cognitive archaeology. Willey consistently took theoretical stances that were not dogmatic or rigid, but rather flexible and pragmatic.

Winckelmann, Johann Joachim

A. A. Donohue
Department of Classical and Near Eastern Archaeology, Bryn Mawr College, Bryn Mawr, PA, USA

Basic Biographical Information

Johann Joachim Winckelmann (1717–1768) is among the most influential founders of the modern disciplines of art history and classical archaeology. Born in poverty at Stendal, in Prussia, his abilities allowed him to obtain a gymnasium

education, followed by unsatisfying university studies in subjects such as theology and natural sciences before he became a reluctant schoolteacher. In 1748, he seized the opportunity to become librarian to Count Heinrich von Bünau at his estate near Dresden, a post that brought him into contact with the lively culture of the city, including the royal collections of fine and decorative arts. He began to study and write on art, and, encouraged by the Papal Nuncio to the Saxon court, Count Alberigo Archinto, he converted to Catholicism and in 1755 went to Rome. There his reputation grew among artistic and papal circles. In 1763, he won the important posts of Commissario delle Antichità della Camera Apostolica (papal antiquary) and Scriptor Linguae Teutonicae (responsible for German-language manuscripts in the Vatican Library). His writings won him international fame that extended far beyond the scholarly audience. While returning to Rome from Vienna in June 1768, he was murdered at Trieste.

Major Accomplishments

Winckelmann's importance derives primarily from his publications on ancient, especially classical, art. His first publication, *Gedancken über die Nachahmung der griechischen Wercke in der Mahlerey und Bildhauer-Kunst* (*Reflections on the Imitation of Greek Works in Painting and Sculpture*), was produced in Dresden in 1755; although he had then seen scarcely any examples of ancient Greek art in person, his essay called for no less than a complete renewal of contemporary artistic and social values through adopting the superior ones of the Greeks. Residence in Italy enabled him to study original works in the collections in Rome and other cities, and in an era when the corpus of ancient monuments was not yet comprehensively organized or available, his publications helped disseminate information about both already-known works and new archaeological discoveries. While he continually insisted on the importance of first-hand examination, often criticizing the work of previous scholars on the basis of his own observations, his own reliance on the textual tradition of the ancient Greek and Roman writers for both documentation and interpretation is clear. His most famous work, the *Geschichte der Kunst des Altertums* (*History of the Art of Antiquity*) of 1764, is built on the chronological and developmental framework established in antiquity and used by the post-antique writers whom he also read, one that valued Greek art over Roman and High Classical works over those of earlier and later periods. Always passionate, frequently polemical, and perpetually an outsider no matter how celebrated, Winckelmann made crucial contributions not only to the academic study of the material remains of classical antiquity but also to the Western classical tradition in the art and culture of his own and subsequent times.

Wobst, H. Martin

Robert Paynter
Department of Anthropology, University of Massachusetts Amherst, Amherst, MA, USA

Basic Biographical Information

H. Martin Wobst (Fig. 1) was born on December 12, 1943, in Eickelborn, Germany, and received a classical education at the Kaiser-Whilhelms-Gymnasium in Hannover, Germany. He arrived in the United States in May 1963 to study classical archaeology at the University of Michigan. After one classical archaeology class in his freshman year, he decided to switch to Anthropology. At Michigan, he earned his B.A. in 1966, his M.A. in 1968, and his Ph.D. in 1971. Wobst's dissertation, entitled *Boundary Conditions for Paleolithic Cultural Systems: A Simulation Approach*, was directed by Robert Whallon, a student of Lewis Binford. He became a member of the faculty of the Department of Anthropology of the University of Massachusetts Amherst in 1971. Wobst retired from full-time teaching in the fall of 2010 after a remarkable career as an internationally recognized scholar, a superb teacher, and an effective administrator.

Wobst was a member of the faculty at the University of Massachusetts Amherst who ushered the anthropology department onto the national and international stage, developing its reputation for European Studies, for biocultural anthropology, and for its theoretically informed archaeology. He served as department chair from 1978 to 1984, and again in 1988. He nurtured generations of graduate students as the long-term Graduate Program Director of the department's committee-based student-centric program, in his seminars on Theory and Method in Archaeology, Professional Anthropology, and Indigenous Archaeology, and in his hours of one-on-one advising. He chaired more than 25 completed Ph.Ds and 30 completed M.As, and was a member of approximately 100 committees.

Wobst, H. Martin, Fig. 1 H. Martin Wobst

Wobst is best-known as an archaeological theorist and a strong advocate for indigenous rights and participation in higher education. He has worked with indigenous students, young professionals, and community members in their efforts to transform archaeology, including by raising travel funds for attendance at the World Archaeological Congress (1999) and the American Anthropological Association (2000), as Chair of the Funding Committee of the World Archaeological Congress (2004), as a Founding Member of the Doctoral Program in Indigenous Archaeology at the University of Catamarca, Argentina, and as a Research Team Member of the Intellectual Property Issues in Cultural Heritage Project (IPinCH) of Simon Fraser University (2009-present).

Major Accomplishments

Wobst has made and continues to make major intellectual contributions to the theory of materiality, exploring its implications for all forms of human culture. His often cited "Stylistic Behavior and Information Exchange" (Wobst 1977) developed a

general theory of style as information exchange, analyzing Yugoslavian folk costume by way of example. It is one of the foundational papers in archaeology's move away from the New Archaeology's focus on energetics and toward a more holistic understanding of culture process.

He incorporated agency in this theory by conceiving of material culture as "product of and precedent for" cultural action, and has most recently pursued this line by considering material culture as an "intervention" in ongoing social and ideological processes (Wobst 1999, 2006). Published for his professional colleagues, these concepts also formed the basis for his very popular undergraduate course on the "Archaeology of US," that taught students how to question our culture's taken-for-granted ways conveyed, for instance, in the arrangement of seating in classrooms, the location of sidewalks and informal paths on the campus, and the furnishings found in women's, men's and gender-free bathrooms (Wobst 2007). The study of how humans manufacture, use, and think about material culture was for him the encompassing and distinctive definition of the field of archaeology.

His second major area of contribution was to broaden the discipline's understandings of hunter-gatherer/band/egalitarian ways of life. He challenged the field, through intricate computer simulations and abstract thought experiments, to move beyond tacit culture-bound preconceptions that ancient hunter-gatherer life was small scale, repetitive, and dull, instead offering on the basis of reasonable scientific assumptions that this way of life was and is constituted by lives filled with considerable variety, enmeshed in complex social processes, full of action and imagination. A major foil to illustrate these points was the European Paleolithic, of which his working knowledge of 13 languages gave him unusual scholarly command. Surveying the portable artifacts, rock art, and settlement systems of the Paleolithic, his articles pointed to heretofore underanalyzed dimensions of material variability that could only be accounted for by imagining dynamic and diverse ways of life (Wobst 1974a, b, 1976).

To these areas Wobst has added theoretical and institutional contributions furthering indigenous archaeology. He has coedited two foundational volumes on the topic, one of original papers with Claire Smith (Smith and Wobst 2005) and another that compiles key articles and excerpts in the development of indigenous archaeology with Margaret Bruchac and Siobhan Hart (Bruchac et al. 2010). In these volumes, and in other venues, his contributions point out how and why archaeology is better archaeology when it engages indigenous peoples, be they in the Australian desert, the Arctic tundra, the former Soviet Union, or his community of Leverett, Massachusetts (Wobst 2005, 2010).

Wobst is widely known for his razor-sharp and often amusing analyses, qualities that make him one of his generation's commentators par excellence. His articles, afterwords, professional presentations, and discussant's comments capture archaeology's historical trends and contemporary interests, dissect their internal contradictions, comment on their unexplicated frames of reference, and show that human culture is capable of extraordinary variability. For Wobst, the future of the discipline lies not in establishing new orthodoxies, but in continually pushing at the boundaries of how archaeology understands the breadth of the human experience through the distinctive lens of our creative materiality.

Wolpoff, Milford H.

Catherine Amy Bland
Department of Archaeology, Flinders University, Adelaide, SA, Australia

Basic Biographical Information

American anthropologist Milford H. Wolpoff was born in 1942 to Ruth (Silver) and Ben Wolpoff in Chicago, Illinois. He was educated at the University of Illinois in the field of physical anthropology, evolutionary biology, and ecology and was a student of Eugene Giles. He was awarded a bachelor degree from the University of Illinois, Urbana, in 1964. In 1969 the University of Illinois awarded him a Ph.D. on the basis of his dissertation, Metric Trends in Hominid Dental Evolution. He has been at the University of Michigan, Ann Arbor, since 1971. Since 1977 he has held the position as Professor of Anthropology at the University of Illinois.

Milford H. Wolpoff is an Honorary Life Member of the Honor Society of Phi Kappa Phi and a Fellow of the American Association for the Advancement of Science. In 2011 he won the Darwin Lifetime Achievement Award of the American Association of Physical Anthropologists as well as the Honorary Member of the Golden Key International Honour Society.

Major Accomplishments

Milford H. Wolpoff has made major contributions to both the research and teaching of

paleoanthropology. He is the author of *Paleoanthropology*, which has been the leading textbook for undergraduate and graduate courses in human evolution since it was first published in 1980. He is the coauthor, with Rachel Caspari, of R*ace and Human Evolution: A Fatal Attraction*, which reviews the scientific evidence and conflicting theories of human evolution and how these interpretations are related to views about race.

Much of Professor Wolpoff's research focuses on the evolution of European Neanderthals (e.g., Wolpoff 2009), the role of culture in early hominid evolution, the nature and explanation of allometry, robust australopithecine evolution, the distribution and explanation of sexual dimorphism, hominid origins (Wolpoff 2002), the pattern and explanation of Australasian hominid evolution, the contributions and role of genetics in paleoanthropological research, and the taxonomy of the genus Homo.

Milford H. Wolpoff's major contribution to paleoanthropology is the development of one of the two most recognizable theories in human evolution – the multiregional model. His basis for advancing the multiregional interpretation of human evolution derives from his disbelief in punctuated equilibrium, the idea that changes occur when new species are formed and only rarely are slowly and gradually accumulated during the stable periods between species, as an accurate model for Pleistocene humanity, noting that speciation played a role earlier in human evolution.

The multiregional theory is a scientific model that provides an explanation for human evolution. In his vision, multiregional evolution describes evolution within a widespread species by normal evolutionary mechanisms (Wolpoff 2004). This differentiates from the replacement theories that he believes describe evolution between species, within changes at the time of speciation, as one species replaces the other.

The theory suggests that humans first arose near the beginning of the Pleistocene, about two million years ago, and successive human evolution has been within a single, continuous human species. This continuous human species includes archaic humans including *Homo erectus* and Neanderthals and evolved worldwide to the diverse populations of modern *Homo sapiens sapiens*. This theory suggests that humans evolved through a combination of adaptation within various regions of the world and gene flow between those regions. Supporters of the multiregional origin find supporting evidence in the fossil record, genetics evidence, and the continuity of archaeological cultures as support for this theory. Wolpoff and his colleagues first published the multiregional evolution in 1981 (Thorne and Wolpoff 1981), before the current understanding of mitochondrial DNA and nuclear sequencing in place. Finally it should be noted that Wolpoff's studies of migrations and gene flow out of Africa in human evolution prefigured the out-of-Africa theory of human evolution.

Wood: Conservation and Preservation

Nicola Macchioni
CNR – IVALSA (National Research Council of Italy – Trees and Timber Institute), Sesto Fiorentino, Italy

Introduction

Archaeological wood is a wood with a recognized archaeological value (UNI 11205: 2007). The archaeological value is due to a recognized cultural value. Being strictly related to cultural heritage, the material itself is somehow connected to artefacts partly or completely made of wood. Ancient trunks or stem portions (or even roots or branches), not in strict relation with an ancient artefact, however, must be considered as archaeobotany.

Wood is a biodegradable material because it can be destroyed by some categories of living organisms, such as insects, fungi, marine borers, and bacteria (from the most to the less aggressive). Nevertheless, archaeological artefacts made of wood, preserved in the world' museums, are not rare and the wood itself must be conserved in order to preserve the artefact.

Archaeological wood artefacts fall under two different categories: dry archaeological wood and waterlogged archaeological wood. The first comes not from underground or underwater typical excavations but from aerial dry environments (Fig. 1a): an important example is the desert areas for ancient Egyptian objects; in these situations, wood is protected by dry conditions against fungal attacks. More frequently found, however, are the artefacts of the latter category, waterlogged archaeological wood, coming from underwater or terrestrial, but below the water table, excavations (Fig. 1b). In this peculiar environment, wood is protected against insect and fungal attacks by the waterlogged conditions; moreover, the frequent low oxygen availability slows down even the rather slow bacterial attack (Florian 1990).

Wood: Conservation and Preservation, Fig. 1 (**a**) A coffin of dry archaeological wood from the cliff tombs in Longhushan (China, VII – IV cen. B.C.); (**b**) one of the three Roman ships found in an excavation in the center of Naples (Italy, I cen. B.C.)

In the other excavation environments, it is very rare to find wooden archaeological objects because the conditions are aggressive toward the material that is then transformed into humic substances within decades.

Wooden artefacts can be found even as charcoal artefacts. But in those cases, wood has been already transformed into a different material and the conservation of charcoal will not be discussed here.

Definition

Wood conservation is defined as the guaranteed operations on wooden cultural heritage through a coherent, coordinated, and planned activity of study, prevention, maintenance, and restoration applied to archaeological wood constituting in total or partially archaeological artefacts (UNI 11205: 2007). The preservation is aimed to extend the life of the conserved artefacts as much long as possible. From the methodological point of view, the whole conservation of ancient objects previews three different phases: analyses, conservation, and preservation.

Key Issues/Current Debates/Future Directions/Examples

The key issues and current debates within this discussion are strictly linked to the three aforementioned phases of conservation. But, before that, wood protection and conservation starts within the excavation site.

According to the ICOMOS Charter on the Protection and Management of Underwater Cultural Heritage (1996), once the presence of wood has been identified, if it is not absolutely necessary, retrieval must only be carried out if suitable conditions for safeguarding the wood can be ensured beforehand. In advance, the real economic and technical possibilities for carrying out the following operations in a given time frame must be verified: characterization of the site where the wood is found, storage in suitable and controlled microclimatic conditions, and the characterization of the wood, restoration, possible showcasing in temporary exhibitions, and/or museum use. Where resources are deemed insufficient, retrieval must be postponed and only the documentation and implementation of the suitable measures for protection and temporary conservation must be undertaken.

Wood needs specific care during the retrieval. Before carrying out retrieval operations, measures to protect it from direct radiation and high temperatures (with screens, roofs, and constant spraying in the case of waterlogged wood) must be put in place, and the level of water, if present, must be regulated (with suction pumps etc.) so as to operate in controlled environmental conditions.

If wood comes from confined subaerial sites and underground sites of environments characterized by a dry climate, an apparently unaltered appearance of the wood must not lead to underestimating the importance of caution in the retrieval phase. The general rule applies also in these cases, that is, to prevent the wood from being exposed to sudden variations of relative humidity in order to avoid drastic shrinkages or swelling that can lead to deformations and breakages. Therefore, there is a basic importance to thermo-hygrometrical control the site and the environment in which the artefact is placed after it has been retrieved, so as to put in place systems to enable wood to gradually reach equilibrium in the new conditions, without undergoing damage. It is also necessary to implement measures to guarantee the preservation of wood from biotic attacks. The addition of a suitable biocide must be subject to the evaluation by expert sectorial technical-scientific personnel.

The retrieval of waterlogged wood must be carried out avoiding the evaporation of water from the wood. It is preferable that small size wood be placed in hermetic containers, possibly incorporating sediment and a quantity of water adequate to maintain the waterlogged conditions. For large size wood requiring more time for retrieval, it must be constantly wet to avoid irreversible damage. Since the presence of water in wood in conditions in which it is exposed to environmental contaminants constitutes a factor of high risk for biological colonization, particular attention must be paid to preserving wood.

Then, a characterization is necessary in order to define in qualitative and quantitative terms the degradation undergone by wood and the mechanisms and agents that caused it. This operation has crucial diagnostic value in the preparatory, fact-finding stage, in order to design a project that aims to make suitable choices for the conservation of wood.

Wood characterization cannot operate in isolation from knowledge of the peculiarities of the site

where it lies and the environmental parameters during excavation to be identified (an example can be found in UNI 11206: 2007 "Cultural heritage – Archaeological and archaeo-botanic wood – Guide lines for recovery and first conservation").

Keeping in mind that when possible, while characterizing wood noninvasive enquiries take precedence, sampling must be carried out so as to gather significant data with the least removal of material. The sample must be conserved in containers that are suitably sealed and closed so as to maintain the original humidity of the wood. In the case of waterlogged wood, the sample must be conserved in water that is microbiologically pure. The sample must be maintained in conditions that are unfavorable to biological growth ($T < 4$ °C, no light). The sample must preferably be taken, insofar as possible, from preexisting fractures or surfaces that are not visible. When sampling during excavation, the sample must be taken in the context of the recovery of the wood. The size of the sample depends on the type and number of enquiries laid down. In sampling operations, the environmental parameters of the site in which the wood was found must be noted.

Wood characterization supplies data for the definition of its state of conservation and for carrying out technological evaluations. These characterizations must include at least (Macchioni et al. 2012):

- Wood species identification, through macroscopic and/or microscopic observations.
- Macroscopic description, to define the morphometric characteristics of wood, of some technological characteristics (presence of sapwood and defects, such as, e.g., knots), of the presence of carbonization, traces of workmanship, etc.
- Micromorphological characterization of the anatomical features that define the state of wood such as the effects of abiotic and biotic degradation. In the case of biodegradation, the entity of degradation of wood must be evaluated, and the typology of attacks by organisms (insects, molluscs, crustaceans) and microorganisms (bacteria, fungus) must be distinguished.
- Chemical analysis aimed at determining chemical components of wood residue apparent in quantitative and qualitative results. Quantitative results define the amount of residue of both organic (in particular, cellulose, hemicellulose, holocellulose; lignin, organic extractives; some aqueous extractives) and inorganic nature (in particular, some aqueous extractives, ashes). Qualitative results identify chemical alterations undergone by the constituents of wood. Chemical characterization of mineral contents enables defining the diagnostic framework. Each evaluation must be carried out on the basis of comparison with analytical results obtained from the same unaltered species of wood recently.
- Physical analysis in which humidity and density values of wood are determined. In the particular case of waterlogged wood, the volume mass must be determined as basic density and residual basic density; moreover, the maximum content of water and equilibrium humidity must be determined.

On the basis of the obtained results, it will be possible to produce a diagnostic report, aimed to take any decision on conservation of archaeological wood.

The suitable choices to conserve wood could then be divided into three branches:

1. The general state of preservation of wood is good/very good, and the future preservation environment is quite similar to the previous one, that is, before retrieval. The decision must be that deep consolidation treatments are not necessary, eventually just a surface makeup.
2. The general state of preservation of wood from the anatomical, physical, and chemical point of view is not good, and the future preservation environment of the artefact is completely different from the previous one. A consolidation treatment can be necessary. The artefact

typology, the diagnostic report, and the future preservation of environment will suggest the most suitable treatment, in terms of materials and methods.

3. The general management of the excavation site, the financial constraints, the lack of scientific support to perform a consolidation treatment, the lack of decision chain in terms of future preservation/exhibition of the artefacts are all elements that could support the decision of an in situ preservation activity for wooden objects. The excavation site and the relevant wooden artefacts are recorded and then reburied, both in terrestrial and underwater sites.

More in depth:

1. Deep impregnation treatments on a porous material, and particularly on wood, can never be considered really reversible. The only achievable results are a reduction of the concentration of the consolidant or the retreatability of the new composite made of wood and the consolidant. The future behavior of the new composite during time (at least decades or centuries), its physical and chemical stability, is never completely foreseeable; thus, the consolidation of a wooden artefact through a deep impregnation must be planned only when it is absolutely necessary.
2. In waterlogged archaeological wood, when the anatomical, physical, and chemical decay is high, the reduction in thickness and in strength of the wood cell walls is high, and the pressure of water ensures the maintenance of the shape of the cells, and in last analysis of the whole artefact. The loss of water during an eventual air drying frequently causes partial or total collapsing of cells and the partial or total loss of the original shape of the artefact (Fig. 2).

Consequently, the conservation of waterlogged archaeological wood involves the removal of water by means of treatments whose goals, as suggested by Grattan and Clarke (1986), can be summarized in the ability of the treatment to stabilize shape and dimensions of the artefact and the ability of the artefact (by means of the treatment) to withstand the future preservation environment. Moreover, the approach to conservation must also ensure the safeguarding of physical integrity of wood and, as much as possible, of its mechanical properties, when the wooden findings consist of large-sized structures with a

Wood: Conservation and Preservation, Fig. 2 Transverse section of elm (*Ulmus* sp.) wood by SEM. The fiber cell walls have been destroyed by bacterial attacks

complex architecture, made of several wood species differently decayed. Various methods have been tested and used so far for the conservation of degraded waterlogged wood (Giachi et al. 2010, 2011). Recently, Hoffmann (2009) compared some of the treatments currently most used and found that whereas the success of a stabilizing intervention depends on several factors, each method presents advantages and disadvantages. Generally, a compromise between contingent conservation exigencies, maintenance requirements, costs, safety, and easiness of procedures is chosen. At present, the most used techniques to conserve waterlogged archaeological wood are based on the impregnation of artefacts by natural or synthetic products, which penetrate into the objects through the diffusion and permeation processes (Grattan and Clarke 1987). Treatments using PEGs [polyethylene glycols of various molecular weights (Fig. 3)] are by far the most diffused, although methods using sucrose and other sugars (Cott and Strigazzi 1999) and more recently sugar alcohols (Zhang et al. 2009) and Kauramin®, a melamine resin (Wittköpper 1998), are also used. A new methodology through a "gentle" controlled drying in vacuum chambers is taking off (so far there have been no scientific studies published on this methodology).

3. Reburial in terrestrial environments and covering with natural or artificial sediments in underwater excavations must be designed with particular accuracy because the goal must be the obtaining of the same conditions that ensured the conservation of the artefacts before the excavations. Particular care must be paid to the oxygen availability and the risk of quick and highly destroying fungal attacks in terrestrial excavations, while, in underwater marine excavations the risk of quick destroying attacks is from marine borers, especially from shipworms (*Teredo* sp.). The presence of a thick (at least 50 cm) layer of sediment reduces the oxygen availability and protects from the shipworms attacks (Björdal and Gregory 2011).

The artefacts, treated or not, reburied or not, will need continued maintenance that must be designed together with the treatment methodology.

Wood is a hygroscopic and anistropic material and it maintains these features through time. Its treatment with different chemical consolidant can vary, but not block, the eventual and

Wood: Conservation and Preservation, Fig. 3 Transverse section of a fir (*Abies* sp.) archaeological samples treated with PEG 400 and 4000. The treatment both consolidates degraded cell walls and fills some cell lumens

differentiated movements of wood due to thermohygrometric variations of the environmental conditions. As such, the chemical stability of untreated and mostly of treated artefacts needs continuous monitoring because the real behavior of a new composite made of decayed wood and consolidant cannot be completely foreseeable. Such was the case of the warship Vasa, which is well known and has been scientifically described in several Ph.D. thesis, papers, and books (e.g., Sandström et al. 2002). Additionally, wood is a biodegradable material and the component of the cell walls can be severely degraded by new attacks on already degraded cells of archaeological wood. The new eventual components added to wood for preserving artefacts could avoid new attacks, but also cause new ones. In the end, the stability of the treated artefacts must be controlled through time and the design of the preservation treatment should precisely describe the analyses to be made and their timing.

State of Knowledge and Current Debates

Introduction

Since the early days of North American archaeology, one area of particular interest has been the North American heartland, which is found in the Midwest and Midsouth of the continent, stretching from the eastern margins of the Great Plains to the Appalachian Mountains (Fig. 1). The first Europeans venturing west of the Appalachians encountered thousands of mounds, enclosures, and other earthworks in this area, which stood as testaments to the ancient people who lived in these regions. At first these constructions, many of which were laid out with startling geometric precision, were attributed by some European Americans to a lost race of mound builders, who perhaps had been eradicated by the indigenous people then inhabiting the area. Although some of the earliest students of archaeology in North America, including Thomas Jefferson, concluded that these constructions were built by the ancestors of American Indians, it

Woodland and Mississippian Cultures of the North American Heartland, Fig. 1 The heartland region showing the location of key sites

W

was not until the end of the nineteenth century that the debate about who the mound builders were was settled, and these mounds were understood to have been built by Indians. Deprived of popular fantasies about lost races and ancient wonders, the public became much less interested in the mounds and earthworks of the heartlands. Progressively, many of the tumuli were destroyed for the fill dirt they contained or in order to make farming of the land easier during the nineteenth and twentieth centuries.

Today, most Americans know very little of the mounds and earthworks of the heartland, and the preservation of those remaining is threatened. Even those who do know of a particular mound group have little understanding of the cultural context in which mounds and earthworks were built. Instead, superficial and stereotypical ideas about "primitive" or "ecological" Indian tribes of the heartland are common.

Nevertheless, at first stimulated by early debates about mound builders and their origins, but then carried on by the universities and museums of the area as well as under government auspices and through contemporary CRM projects, the archaeology of the heartland has been an important focus for American archaeologists since the late nineteenth century. Not only have archaeologists learned about mounds, earthworks, and their constructions, but the cultural sequence for the area now is well understood. The lifeways of people inhabiting this area in the pre-Columbian past have been partially delineated. Archaeologists working in the heartland also contribute significantly to theoretical and methodological debates within American archaeology. Between 1000 BCE and European contact, two broad periods generally are recognized for the heartland. These periods, the Woodland and the Mississippian, which encompass much of the time when significant mound and earthwork construction took place, are the focus of this entry.

History of Concepts

By the 1930s, North American archaeologists generally agreed that there were two broad pre-Columbian Eastern Woodland pottery making patterns both of which were associated with more sedentary lifeways and possibly horticulture. These were called the Woodland pattern and the Mississippian pattern by McKern (1939: 309) and distinguished on the basis of trait lists. A further attempt to define the Woodland pattern was made at an archaeological conference held in Chicago in 1941 when a more detailed list of Woodland traits was constructed that was linked to semi-sedentary lifeways; grit-tempered, cord-marked pottery of subconoidal form; and stemmed or notched projectile points. In contrast the Mississippian pattern was believed to be distinguished by sedentary lifestyles; shell-tempered, incised, or modeled pottery in various shapes; and small triangular projectile points.

As archaeologists grew more interested in human adaptations and adopted more explicitly evolutionary models of the past, the concepts of the Woodland and Mississippian patterns were reformulated. Archaeologists came to recognize a Woodland period, extending from approximately 3,000–1,000 years ago, and a Mississippian period beginning around 1,000 years ago each with different lifeways. The Woodland period was associated with the appearance of pottery and burial mounds as well as with the first evidence of horticulture. It was also generally subdivided into Early, Middle, and Late subperiods with the Early Woodland marked by the initial appearance of pottery and burial mounds and the Middle Woodland distinguishing the era of Hopewell cultural developments and interaction (see below). In heartland taxonomic sequences, the Late Woodland usually was described as an interlude between Hopewell and Mississippian fluorescences. Outside the heartland, where Mississippian culture did not develop, the Late Woodland period, more often than not, was understood to continue until contact with Europeans. The Mississippian period distinguished societies that were dependent on agriculture and, thus, fully sedentary. It was also characterized by population growth and aggregation, social ranking, specialization of labor, and elaborate religious ceremonies.

The seminal formulation of Willey and Phillips (1958) placed the Woodland and the Mississippian into an evolutionary scheme by insisting that these patterns were stages of cultural development rather

than periods. While these authors viewed the Early Woodland as at an "Archaic level" of development, Middle Woodland and later cultures of the Eastern Woodlands including the Mississippian were presented as examples of the Formative Stage. This stage had two central defining characteristics: agricultural economies and settled village life.

Today North American archaeologists use the concepts of Woodland and Mississippian periods and stages more or less interchangeably, overtly ignoring the evolutionary implications of these designations even while implicitly accepting many aspects of the formulation. There is a general understanding that the peoples of the heartland after roughly 3,000 years ago used pottery, built mounds, and engaged in elaborate mortuary ceremonialism while living in more or less sedentary villages and growing both native and tropical cultigens as parts of mixed economies that also incorporated many wild resources. These people are also understood to have participated in regional trade networks that moved raw materials, foodstuffs, and finished goods to great distances. Significant population growth and aggregation are believed to have characterized the Woodland and the Mississippian. Although data now indicate both considerable variability in Woodland and Mississippian societies and economies and the presence of "Woodland traits" during the preceding Archaic period, Woodland and Mississippian remain important general concepts for heartland archaeologists.

Woodland and Mississippian Cultures of the North American Heartland, Table 1 Temporal breakdown of the Woodland and Mississippian periods in the North American heartland

Cultural period	Subperiod	Approximate dates
Mississippian	Late Mississippian	AD 1400–1550
	Middle Mississippian	AD 1200–1400
	Early Mississippian	AD 1000–1200
Woodland	Late Woodland	AD 500–AD 1000
	Middle Woodland	200 BC–AD 500
	Early Woodland	1000 BC–200 BC

The Woodland

As mentioned above, the Woodland period in the heartland of North America is typically broken down into Early, Middle, and Late periods (Table 1). The Early Woodland period is usually dated from approximately 1000 BCE to 200 BCE, while the Middle Woodland period includes the interval between approximately 200 BCE and CE 500. There is some variation within the heartland in dating with some authorities starting the Middle Woodland closer to 100 BCE and some not ending it until CE 600. The Late Woodland period follows the Middle Woodland interval and extends until around CE 1000 in the heartland, although in adjacent nonheartland areas Late Woodland persists to contact with Europeans in the sixteenth century.

Early Woodland

Early Woodland people in the heartland have sometimes been characterized as having Archaic adaptations with pottery, but this is an oversimplification of complex, time-transgressive, and variable changes. The first pottery in the Eastern Woodlands was produced along the Atlantic Coast in parts of the Carolinas, Georgia, and Florida during the Archaic period. However, this innovation did not quickly diffuse over the heartland. Instead, the adoption of ceramic technologies was a slower time-transgressive process that could have been influenced by the production, exchange, and use of steatite (soapstone) bowls (Sassaman 2002). Alternately, steatite bowls could have had a specialized purpose, possibly processing certain mast (nuts) for consumption (Truncer 2004). Vessels, bowls, and bottles made out of gourds, wood, and basketry also might have contributed to the slow adoption of pottery. Some peoples in the heartland did adopt pottery earlier than others, which may reflect lower mobility, new land tenure systems, and/or the incorporation of new subsistence strategies. Notably by approximately 1500 BCE, Late Archaic people living along the middle Tennessee River were making pottery. By the beginning of the Early Woodland period, most groups in the heartland were

probably aware of how to produce pottery. Yet it is unclear how much pottery some Early Woodland people made and whether it was central to their lifeways.

While many Early Woodland people were mobile hunter-gatherers, who probably did not construct permanent structures, some sites suggest a greater degree of permanence. Similarly, some groups supplemented earlier subsistence practices with various indigenous domesticates such as goosefoot (*Chenopodium berlandieri*), knotweed (*Polygonum erectum*), sumpweed (*Iva annua*), sunflower (*Helianthus annuus*), and squash (*Cucurbita pepo*). Several cave sites in northwest Arkansas and eastern Kentucky contained caches of these domesticated seeds (Fritz 1993). Nuts were also important foodstuffs because they could be gathered by the bushel in a good year and placed in storage pits to be eaten during lean seasons. People hunted white-tailed deer (*Odocoileus virginianus*), rabbit (*Sylvilagus floridanus*), raccoon (*Procyon lotor*), squirrel (Sciurus spp.), and wild turkey (*Meleagris gallopavo*). Many Early Woodland groups also fished, hunted waterfowl, and collected freshwater mussels and other aquatic fauna.

Many aspects of Early Woodland life were remarkably similar to earlier lifeways. Yet Crothers (2012: 525) has argued that "new forms of social and economic relations emerged panregionally with the development of the first horticultural economies." It appears that many Early Woodland peoples placed an emphasis on establishing and conducting complex ritual regimes, which may have included masculine initiation ceremonies in certain caves (Crothers 2012) and rituals associated with menstrual retreats in rock shelters (Claassen 2011) as well as the elaborate treatment of the dead at specific regional centers that archaeologists have long recognized. The interactions at these regional centers presented opportunities to "work out" competing claims on the social persona of the living and dead, as well as opportunities to feast, negotiate alliances, smoke pipes, exchange goods, play games, and possibly acquire brides/grooms from other social groups.

Early Woodland mortuary regimes had considerable continuity with earlier practices from the Terminal Archaic period, c. 2000–1000 BCE. For example, the Glacial Kame and Red Ocher mortuary complexes straddle the transition between the Late Archaic and Early Woodland periods. The Glacial Kame mortuary complex, of Illinois, Indiana, Ohio, and further north around the Great Lakes, derived its name from the practice of placing the dead in gravel ridges or kames left by glaciation. These burials usually were tightly flexed inhumations in circular pits that were covered with red ocher and sometimes included elaborate ceremonial objects, such as sandal-sole shell gorgets, circular shell gorgets, bar gorgets, birdstones, tubular pipes, wolf and bear masks, and copper and shell beads. The Red Ocher mortuary complex refers to burials in Indiana, Ohio, and Michigan that were covered in red ocher and associated with diagnostic turkey tail points. These bodies were sometimes covered by low artificial mounds and interred with cache blades and tubular pipes. The deposition of large caches of ceremonial objects, such as turkey tail points and cache blades, is a notable development associated with the Red Ocher complex because it portends some later Early/Middle Woodland rituals. While historically these two "types" of sites have been considered distinct, it is probably more apt to refer to Red Ocher and Glacial Kame as similar regional interaction spheres.

After 500 BCE, the construction of burial mounds and associated earthen enclosures accelerated, especially in portions of Ohio, Kentucky, and West Virginia. Many of these mounds and enclosures are associated with the Adena taxon. This association is unfortunate because the Adena mound, located near Chillicothe Ohio, is a poor type site. It is composed of a primary and a secondary mound and there are significant differences between the artifacts interred in these components. New AMS dates from Burial 20, a log crypt dug into the primary mound, place the earlier component at the Adena-type site, circa 100 BCE to 100 CE (Lepper et al. 2014). These dates from Adena indicate that the primary mound was contemporaneous with the early Middle Woodland (Hopewell) Tremper Mound, located

further south in the Scioto River Valley. The secondary mound (Adena type-site) is therefore coeval with later Middle Woodland components. Heartland archaeologists therefore need to reassess the Adena taxon and perhaps even adopt new approaches to variable mortuary programs throughout this part of the Woodland (Clay 2014).

Mounds associated with the Adena taxon typically date after 500 BCE and extend into the Middle Woodland period. Adena burial mounds are notoriously complex and variable. These mortuary regimes often begun with some sort of charnel structure, crypt, or screened area; whose use was discontinued when the facility was mounded over. Circular "paired post" structures were a common feature at the base of Adena mounds. Some of these paired post structures were quite large and it appears unlikely that they were roofed, given the absence of central support posts. Circular earthen enclosures, colloquially dubbed "sacred circles," are also often associated with Adena. These earthen enclosures generally have a moat-like outer ring that was bridged by a narrow gateway and an interior earthen embankment. A mound was sometimes constructed inside these earthen rings, and in particular cases, it grew so large that the underlying circular embankment was no longer visible.

Adena burial mounds were sometimes accretional tumuli with log tombs or crypts dug into the primary mound. Deceased individuals were interred in these log tombs and then the mound was capped with additional soil. Some Adena mounds became quite large due to the addition of many accretional burials and soil mantles. There is also considerable diversity in Adena interment styles, since extended burials, cremations, and bundle burials can occur in the same mound. Some of these burials were interred with various objects, including stone axes, gorgets, pendants, celts, mica crescents, copper beads, shell beads, pearl beads, tubular pipes, animalistic headdresses, and copper bracelets and rings.

Elaborately carved stone and clay tablets are considered diagnostic of Adena, but it is notable that four serpentine examples were found in Mound 1 at the Middle Woodland, Hopewell type-site located near Chillicothe, Ohio. A close examination of the primary evidence reveals that most of these tablets derived from poorly dated contexts so assigning them to a particular period is problematic. Nevertheless, these small rectangular, engraved tablets portray a rich assortment of iconographic imagery, including raptorial birds, human–bird hybrid beings, and other types of images. These tablets were often interred with bone awls and/or various pigments. The bone awls seem to correspond to the grooves found on the back of many of these tablets, which suggests they were used to sharpen the awls. Archaeologists have suggested that these tablets could have been used in two ways. First, these tablets may have been used to stamp the illustrations they bear onto clothing or other objects. Second, they may have been part of tattooing kits, which posits that the bone awls were sharpened on the tablets and dipped into the pigments. The bone awls were then used to impregnate different areas of the body with tattoos.

Middle Woodland

Archaeologists date the beginning of the subsequent Middle Woodland period earlier in some parts of the heartland than in others. This is because many of the diagnostic traits used to mark the Early–Middle Woodland transition are time-transgressive traits that occur earlier in particular areas and later in others. For example, the Early Woodland (Tchefuncte/Tchula) people of the Lower Mississippi River Valley produced ceramic vessels with curvilinear incising and rocker stamping: two attributes that are often used to differentiate Middle Woodland, Hopewell assemblages. Some of the most characteristic motifs are incised depictions of raptors and ducks on ceramic vessels (Fig. 2). Middle Woodland, Hopewell people in Illinois also produced similar pottery styles by around 200 BCE. These decorative techniques were only later adopted by peoples in southern Ohio, as well as in other parts of the heartland. In many areas of the central Ohio River Valley, Middle Woodland groups simply continued to make pots very similar to those they traditionally used, a pattern often associated with the continuation of the Adena complex.

Woodland and Mississippian Cultures of the North American Heartland, Fig. 2 Unusual double Hopewell ceramic vessel with raptorial and diving bird imagery from Mound City near Chillicothe, Ohio

While an early perspective was that Middle Woodland, Hopewell people lived in hierarchical societies that had corn-based agricultural economies and permanent villages, subsequent archaeological work has revised our understanding of their lifeways. Settlement surveys have found little evidence of domestic dwellings among Ohio Hopewell earthworks. Instead they have documented the presence of small, dispersed occupations that served as sedentary farmsteads or nodes in more itinerant hunter-gatherer lifeways. Middle Woodland settlement patterns were oriented differently in the Illinois River Valley, since Illinois Hopewell occupations are more regularly spaced and located at the base of bluffs below clusters of burial mounds. Other regions also seem to have dispersed settlements.

Analyses of Middle Woodland subsistence practices generally show continuity with earlier food ways. Nevertheless, increased utilization of indigenous seeds is evident in the Illinois and central Ohio River Valleys. This pre-maize horticulture emphasized the cultivation of oily seeds, sunflower, and sumpweed, as well as small grains like chenopodium, knotweed, maygrass, and little barley. All of these seeds had been cultivated for several millennia, but in Middle Woodland times, they became even more important to some groups (Scarry and Yarnell 2011). The diets of other Middle Woodland peoples do not reflect an increasing use of indigenous domesticates. There are also regions, such as the central Mississippi River Valley, where the diet of Middle Woodland people remains to be delineated.

Middle Woodland mortuary practices also varied considerably, but many Adena/Hopewell funerary regimes involved secondary burial rites. It was during these staged secondary burial rites that Middle Woodland mounds were constructed to cover their charnel precincts. Two important centers of mound building in the heartland region are the Illinois and Ohio Hopewell archaeological complexes, although a number of other regional expressions exist.

Illinois Hopewell is known primarily from the Illinois River Valley, where many burial mounds have been found on bluffs and in the floodplain. The Gibson–Klunk mounds, located along the western bluff line of the Illinois River Valley at Kampsville, Illinois, have been particularly well studied. These mounds had central vaults, often lined with logs, in which the dead were placed and allowed to decompose. Many of these bones were collected and then interred as secondary burials in the corner of the tomb or in a pit along the side of the primary mound (Brown 1979). Some of the dead were interred as primary burials in these crypts. Grave goods were frequently buried with both types of burials. At the end of the ritual cycle, Illinois Hopewell people covered these crypts with mounds. Some status differentiation is evident in the burials, but sex and age rather than heredity seem to be the primary determinants of burial treatment.

Ohio Hopewell people, in contrast, constructed charnel houses to store the dead before they were cremated. These Ohio Hopewell charnel houses were roofed, sometimes two storied, rectangular structures that had rectangular fired clay basins on their floors (Brown 1979). The fired clay basins were constructed from puddled clay and the dead could have been cremated in some of the larger

examples, but they probably also served as multipurpose hearths. Burials along with rich grave goods were placed on the floors of these charnel houses. Large ritual caches, a distinctive feature of Ohio Hopewell rituals, sometimes were deposited in these structures in (or adjacent to) the fired clay basins. Large ritual caches often contained more elaborate objects and ritual paraphernalia than the burials. Ohio Hopewell people razed these charnel structures and constructed a mound over them, which terminated their use. Moreover, on floodplains or alluvial terraces, these mounds often were enclosed within large earthen embankments that were constructed in a variety of geometric shapes and included circular woodhenge structures within them as well as mounds. Ohio Hopewell hilltop enclosures were constructed to conform to the natural topography of hills and summits.

The elaborate paraphernalia found with burials and in ritual caches in Hopewell mounds indicate that increased interaction, exchange, and possibly long-distance forays occurred during the Middle Woodland period. The term "Hopewell Interaction Sphere" has been used to describe this interaction and exchange (Carr and Case 2005; Charles and Buikstra 2006). The movement of specific types of objects and raw materials, including copper, marine shell, and exotic cherts, points to continuity with previous exchange networks. The copper came primarily from northern Michigan and southern Ontario, although a smaller amount was derived from the Appalachian Mountains and other sources. The marine shell likely came from the Gulf and Atlantic Coasts. Various types of chert also moved through Hopewell exchange networks, sometimes in huge quantities, given the large numbers of exotic bifaces found in particular ritual caches. For example, there were caches of over 8000 bifaces made of nonlocal blue-gray chert, found under Mound 2 at the Hopewell type-site.

Other materials were acquired in unprecedented quantities by Middle Woodland people, such as obsidian from the Rockies and mica from the Appalachians. For example, 300 lbs. of obsidian was interred under Hopewell Mound 11 and it appears to have been directly procured from outcroppings at Yellowstone National Park in Wyoming. The direct acquisition of this obsidian is supported by depictions of bighorn rams in Hopewell iconography. Bighorn rams are not local to Eastern North America, but live in the Rocky Mountains near the obsidian sources indicated by recent chemical analyses. Similarly large quantities of mica were acquired by Ohio Hopewell people probably from Middle Woodland groups who lived in the Carolinas. This mica was cut into various forms, such as circles, human hands, and decapitated/dismembered human bodies.

Certain finished objects were exchanged during the Hopewell horizon, such as copper panpipes, copper "reel-shaped" gorgets, Hopewell series pots, and plain and effigy platform pipes. For example, large caches of exquisitely carved Hopewell animal effigy platform pipes were deposited under Mound 8 at Mound City and the Tremper mound, which are located along the Scioto River in central Ohio (Fig. 3). Smaller quantities of animal effigy platform pipes also occur with burials in various other Ohio and Illinois Hopewell mounds. These animal effigy pipes depict a veritable menagerie of different mammals, reptiles, and birds. They represent these animals in a naturalistic style, although some stylized motifs occur. Compositional analyses indicate that these pipes were produced from various sources. Three important sources are Sterling pipestone from

Woodland and Mississippian Cultures of the North American Heartland, Fig. 3 Falcon effigy pipe from the Tremper Mound in Southern Ohio

northern Illinois, Feurt Hill pipestone from central Ohio, and red catlinite from Minnesota and southern Ontario (Emerson et al. 2013).

Recent research also indicates that specific iconographic themes emerged during the Middle Woodland, Hopewell period. For example, Giles (2013) has illustrated that Burial 11 in Hopewell Mound 25 was interred wearing a double-headed raptor headdress that parallels other representations from the central Ohio River Valley, including certain Adena tablets (e.g., the Low Tablet). Some Hopewell iconographic themes and objects also suggest a measure of continuity with Late Woodland and Mississippian symbols, including, (Hopewell) copper earspools, quadriconcave plates, cross-in-circle motifs, human-bird hybrid imagery, and copper falcon repoussé plates (Fig. 4).

Hopewell exchange objects have been found in sites outside the heartland. For example, burial pits excavated at the Mandeville site, a Deptford/Swift Creek tradition site located on the Chattahoochee River in Georgia, contained copper panpipes and earspools, clay platform pipes, prismatic blades, ceramic figurines, mica, and greenstone celts suggesting Hopewell ceremonialism. After approximately 50 BCE, sites in the vicinity of Kansas City to the west of the heartland contain ceramics similar to those from Illinois Hopewell sites as well as other Hopewell objects. The Abbott Farm site, located near Trenton, New Jersey, also contained pottery suggestive of Hopewell in association with mica sheets, argillite and jasper bifaces, conch shell fragments, and platform pipes. Hopewell ideas therefore seem to have influenced many groups outside the heartland during Middle Woodland times (Carr and Case 2005).

Woodland and Mississippian Cultures of the North American Heartland, Fig. 4 Hopewell falcon copper repoussé plate from Mound City, Mound 7 near Chillicothe, Ohio

The Late Woodland

The Late Woodland begins at approximately CE 500, when Hopewell mounds and earthwork complexes were no longer being built. There are a number of places at which terminal Middle Woodland or early Late Woodland people continued to build mounds, such as the Firehouse mound near Cincinnati, Ohio, and the Russell Brown Mound near Chillicothe, Ohio. There also was some rebuilding or repair of Hopewell earthworks during the Late Woodland. Similarly the Hopewell Interaction Sphere appears to have broken down around CE 400–500. However, a more limited interaction sphere continued in the Ohio River Valley that had a more northerly centered distribution in which materials such as mica, shell, and possibly slate were still exchanged (Seeman and Dancey 2000). There are also certain artifacts that seem to indicate continuities with Middle Woodland, Hopewell traditions, such as early Late Woodland Fairfield shell gorgets. The end of the Middle Woodland usually was not abrupt even in Hopewell core regions, and the archaeological taxonomic units associated with this Middle to Late Woodland transition can vary considerably across the heartland. The Late Woodland period ends around CE 1000 when a number of societies in the heartland have characteristics associated with the Mississippian pattern.

Traditionally, archaeologists have considered the Late Woodland period as the time of the "good gray cultures." This designation reflects the idea that the Late Woodland was a drab period of decline, sandwiched between the Hopewell and Mississippian cultural climaxes. More recently archaeologists have viewed the Late Woodland as a pivotal period with considerable variability that was marked by several important transitions.

Late Woodland ceramics were most often plainer than those made during the Middle

Woodland, with cord marking a common surface treatment. The Late Woodland stone tool industry also is characterized by the disappearance of various exotic stone types as well as a reliance on utilized or minimally worked flakes rather than more formal tools. With respect to settlement and subsistence, there was considerable diversity during the Late Woodland period. For example, some Late Woodland peoples had subsistence and settlement strategies that emphasized logistical mobility that was consistent with earlier periods. Other Late Woodland groups began to settle in nucleated communities. In general, groups were probably more mobile during the early Late Woodland interval, but became increasingly sedentary through time. The increasingly sedentary lifeways associated with Late Woodland people may have been a response to overall population growth.

Archaeologists have found strong evidence for nucleated settlements in the Ohio Valley above the Falls of the Ohio. In contrast, settlements decrease in size as the Late Woodland begins in the lower Ohio and along the Illinois drainage. Stonewalled enclosures often called "stone forts" first were made in southern Illinois and Kentucky at this time. The nucleated settlements in Ohio that have moats and fortifications, as well as the "stone forts," may indicate defensive concerns. At the end of the Late Woodland, towns with mounds appear in the central Mississippi Valley, northern Georgia, and other parts of the heartland. Other traits associated with Mississippian societies also emerge at the end of this period. They include the use of shell to temper ceramics, wall trench construction for houses, and intensive maize agriculture (Anderson and Mainfort 2002). Rock art at Gottschall Rockshelter and Picture Cave also indicates the appearance of He-Who-Wears-Human-Heads-As-Earrings and Birdman imagery during the terminal Late Woodland period, iconographic themes that become important during the Mississippian period.

Another Late Woodland development was the widespread adoption of the bow and arrow around CE 700, marked by the predominance of small notched and unnotched triangular projectile points. These points often were made from flakes instead of directly from bifacial cores. Although the bow and arrow may have been known earlier, people now were making predominantly small points that were probably arrow points. This shift to the bow and arrow is significant due to its presumed efficiency as a hunting implement and as a weapon. Archaeologists also debate whether the rise of the bow and arrow was associated with intensified deer hunting or conflict and warfare. Some archaeologists suggest that higher population levels in the Late Woodland caused resource stress and the adoption of second-line resources like small mammals and shellfish.

One response to this competition over resources was to intensify the agricultural production of native seed plants and later tropical cultigens like maize. However, Late Woodland people did not uniformly intensify agricultural production. Within the major Midwestern river valleys, archaeologists have documented intensification of the plant cultivation as evidenced by the widespread presence and large quantities of native seeds. People also used some corn and tobacco, as well as many aquatic resources, including fish species that spawn in river backwaters. However, proportionately lower use of seed plants and greater reliance on white-tailed deer are evident in upland sites.

The end of the Late Woodland period also is marked by the shift to maize agriculture beginning around CE 900–1000. This shift is evident both in the greater amount of maize found in sites and in changes in the C^{12}:C^{13}ratio found in human bone. Minor use of maize has been presumed starting in Middle Woodland times based on recovery of a few macro plant remains, and maize pollen has been dated to the third century BCE further north and east, but re-dating of maize macro-remains from Middle Woodland contexts suggests a much more complicated and variable history of the adoption of maize in the heartland (Simon 2017; Hart and Lovis 2013). Eastern Eight Row or Northern Flint corn, which developed out of existing maize demes in the Northeast, is associated with the spread of maize agriculture, but this too was more variable than archaeologists once thought. Much more detailed archaeobotanical, palynological, and isotopic study will be

necessary to sort out the timing and process of the shift to maize agriculture.

Moreover, beans (*Phaseolus vulgaris*) were not yet present at the end of the Late Woodland. AMS dating of beans from Eastern Woodland contexts indicates that beans did not arrive until approximately CE 1200 at the earliest. Thus, the maize, bean, and squash polyculture that is iconic for American Indians was not yet practiced, and each of these crops has its own history of spread and adoption (Hart et al. 2002).

Mississippian Period

Given the amount of diversity in Late Woodland adaptations, the development of Mississippian cultural phenomena cannot be attributed to the same factors everywhere. However, around CE 1000, a number of groups in the heartland rapidly developed traits that characterize Mississippian societies, including a growing reliance on maize agriculture, shell-tempered pottery, wall trench structures, and aggregated village settlements. Many Mississippian societies became complex political polities or chiefdoms with hierarchical social structures. These polities often were centered on large towns that had public plazas, platform mounds, and residential spaces. Ceremonial structures, possibly the residences of chiefs or elites, were sometimes constructed at the top of Mississippian platform mounds. Mississippian chiefdoms generally first developed in the American Bottom and central Mississippi River Valley and then spread further east until these complex polities extended throughout most of the heartland. There are also some cultural traditions in the heartland that, despite certain distinctions, have been considered regional variants of Mississippian. The most notable are the Fort Ancient societies of the central Ohio River Valley.

The Mississippian period is divided into the Early Mississippian from CE 1000–1200, the Middle Mississippian from CE 1200–1400, and the Late Mississippian from CE 1400–1550 (Table 1). During the Early Mississippian period, the traits associated with Mississippian societies, such as maize agriculture, shell-tempered pots, wall trench structures, and a site layout that included both platform mounds and raised earthen plazas, spread to many regions of the heartland. It was also during the Early Mississippian period that hierarchical chiefdoms emerged. The largest political polity of the period was Cahokia, located east of modern-day St. Louis. Mississippian polities were not particularly stable and their power rose and fell. The Middle Mississippian period marks the height of these polities. In contrast, the Late Mississippian was a time of increased warfare, population aggregation, and political turmoil, as well as decreased mound building.

In some areas, Mississippian societies persisted into the Protohistoric era and certain polities have been linked with the indigenous groups De Soto's expedition encountered between 1539 and 1543 (Cobb 2003). The accounts of the De Soto expedition and other ethnohistoric records are often used as a baseline for the social organization and practices of Mississippian societies (Urban and Jackson 2004). Nevertheless, the arrival of Europeans did create a volatile period with increased violence and epidemic diseases that led to a massive depopulation of indigenous communities. During this turbulent period, the social and political landscape was dramatically transformed as particular peoples were essentially eliminated, while sometimes new ethnicities were created from their remnants. The ethnohistoric evidence also establishes that a number of different languages were spoken. It is therefore clear that Mississippian societies were not one people, but rather different cultural groups that had similar lifeways.

Mississippian people were some of the first easterners to settle in large permanent towns that contained central plazas, public buildings, platform mounds, and encircling stockades. These towns served as centers for political polities that included some outlying farmsteads and hamlets. The size and scale of Mississippian polities varied a great deal, but some of the largest were comprised of multiple towns that were politically aligned together. Some polities probably had one central "power" or chief. Migrations also appear to have been common and some areas experienced quite rapid population increases and decreases. For example, there was an influx of people right before the emergence of Cahokia in the American

Bottom around CE 950. In contrast, the lower Ohio Valley and adjacent areas of southern Illinois and northern Kentucky, as well as western and central Tennessee, were largely abandoned by CE 1450–1500. This area has been dubbed the Vacant Quarter (Cobb and Butler 2002).

Mississippian people were maize agriculturalists who also cultivated native plants and exploited deer, fish, waterfowl, and wild plants. After the Early Mississippian, native cultigens became less important in most of the heartland, and the maize–bean–squash polyculture began to be developed. It has been argued that Mississippian populations were adapted to a specific meander belt habitat in the major river valleys of the Midwest and Southeast, but more recent investigations indicate that Mississippian adaptations were more varied, both geographically and temporally.

On the basis of ethnohistorical accounts, there were probably fairly distinct social roles for men and women in Mississippian communities. Mississippian women were responsible for agricultural production, although men probably helped clear the fields of large stones and trees prior to planting. Mississippian women used stone hoes that were often made out of Mill Creek or Dover chert to till the land. At some sites, like Ocmulgee in Georgia, ridges and furrows associated with prehistoric agriculture have been found. Mississippian men actively engaged in hunting, warfare, and politics. Men in these societies likely earned prestige through hunting, military accomplishments, and/or their skill at negotiating treaties and keeping the peace.

There has been considerable discussion about prehistoric Mississippian politics and social organization. Archaeologists have sometimes classified Mississippian societies into types such as simple, complex, and paramount chiefdoms, but contemporary archaeologists are more interested in understanding these societies' historical trajectories and political economies (Cobb 2003). Some archaeologists believe that long-standing Eastern Woodland beliefs associated with membership in communities and lineages were replaced during Mississippian times with ideologies that elevated particular individuals to hierarchical positions of power. More recently archaeologists have discussed the potential importance of heterarchical or lateral political positions, possibly linked to moieties, clans, age grades, and/or other sodalities (Blitz 2010).

During the Historic period, most heartland societies were organized into dualistic moieties, although there were some specific differences between them (Urban and Jackson 2004). For example, some tribes in the heartland, such as the Creek, were divided into red and white organizations. The red organization dealt with warfare and external relations, while the white organization was more inward-directed and devoted to peace and municipal order. Certain towns were considered as either red or white, although these associations could shift through time as a result of wars and ball game competitions.

Another important subject is the way that different material symbols were linked to particular social positions in Mississippian polities. For example, it appears that Mississippian elites commissioned an array of symbolically charged icons, which asserted their (possibly ancestral) connections to important deities and religious beliefs. These symbols and icons have been referred to as the Southeastern Ceremonial Complex (SECC). SECC objects include elaborate repousse´ copper plates, ornate (sometimes effigy) pots, human and animal effigy pipes, human figurines, "chunkey" stones, chipped stone "swords," stone maces, monolithic axes, and engraved shell gorgets and cups. Many of these Mississippian icons were differentially interred with burials or in ritual caches. The largest quantities of ceremonial paraphernalia were deposited at important Mississippian mound centers, such as Moundville, Etowah, Spiro, and Cahokia. However, the distributions of other symbols, including Mississippian maces, illustrate more varied depositional patterns that included some smaller centers.

In recent years, researchers have focused on understanding Mississippian iconography and linking it to the ethnohistoric beliefs of Native American people. This work has also refined the chronological sequence for SECC representations based on the large elaborate imagery found at four Mississippian mound sites: Cahokia, Etowah,

Moundville, and Spiro. These Mississippian symbols seem to focus on a number of iconographic themes, including warfare, fertility/renewal, eschatology, and cosmology, although there is considerable variation in the subjects represented by these depictions. Abstracted representations of cosmos, such as cross, cross-in-circle, and triskele motifs, are some of the most common SECC symbols (Reilly and Garber 2007). These cosmograms occur in various material media, but most notably on Mississippian shell gorgets that were often pierced for attachment and worn as adornments. Other SECC representations include avian, anthropomorphic, and animalistic "subjects" that probably were associated with the upper and lower worlds in a three-tiered cosmos.

For example, one of the copper Rogan plates from Etowah, Georgia, portrays a now famous representation of a falconoid birdman holding a mace in one hand and a decapitated head in the other (Fig. 5). Similar representations have been found in the Craig Mound in Spiro, Oklahoma, the Castalian Springs site in central Tennessee, and various other Mississippian sites throughout the heartland (Fig. 6). This image almost certainly depicts a warfare-related theme, although it could have as its justification a mythic narrative about the Siouan god-hero: Red Horn or Morning Star (Reilly and Garber 2007).

Utilitarian objects were also produced and exchanged by Mississippian people. For example, Mill Creek chert hoes were made in southern Illinois and then widely exchanged throughout the heartland. There are also several Mississippian sites associated with salt production. Other raw materials, such as copper and marine shell, were widely exchanged by Mississippian people. However, it is not clear how much elite control was exercised over the movement and exchange of these different objects and materials.

Some of the large important Mississippian polities were centered at Cahokia in Illinois, Moundville in Alabama, Kincaid in Illinois, Etowah in Georgia, and Spiro in Oklahoma. Cahokia and Moundville were two of the largest Mississippian sites and usually these are

Woodland and Mississippian Cultures of the North American Heartland, Fig. 5 One of the Braden style copper Rogan plates from the Etowah site showing a birdman holding a mace and a decapitated head (Courtesy Smithsonian Institution)

Woodland and Mississippian Cultures of the North American Heartland, Fig. 6 Braden style birdman holding a mace and a decapitated head on a Mississippian shell gorget from the Castalian Springs Site in Central Tennessee (From Thruston 1890)

interpreted as paramount chiefdoms. Nevertheless, there are important scalar differences between them, suggesting the uniqueness of the larger Cahokian polity (Wilson et al. 2006).

Located across the Mississippi from modern-day St. Louis, Cahokia was the center of one of the earliest and largest Mississippian chiefdoms. Cahokia consisted of at least 104 mounds, a series of large plazas, palisades, and woodhenges, as well as several residential areas. Plazas were large raised public spaces that were periodically cleaned, while the woodhenges were circular wooden structures resembling Stonehenge that may have tracked astronomical events. The mounds at Cahokia were used for a variety of different purposes that included the designation of elite residences, charnel precincts, and other ceremonially charged areas. These mounds included Monks Mound, the largest earthen tumulus in Eastern North America, which is about 30 m (100 ft) high, 291 m (955 ft) long, and 236 m (775 ft) wide with an access ramp on its southern side. Monks Mound is such a large feature of the landscape that you might mistake it for a hill if it were not in the middle of the floodplain.

The Cahokian polity was unique in a number of ways. For example, it encompassed a number of other large Mississippian towns, such as the St. Louis Mound Center, the East St. Louis Mound Center, Pulcher, Mitchell, and Lohmann, and several other small mound centers. Notably, the East St. Louis Mound Group was the second largest Mississippian mound center, while the St. Louis Mound Group was the fourth largest (Wilson et al. 2006). Consequently, the Cahokian polity was larger by a scale of magnitude than any other Mississippian polity. This Cahokian polity actually encompassed an area over 17 times larger than Moundville located in Alabama, which was the largest Mississippian center outside of the American Bottom region. At its height the Cahokia polity probably had a population that was 6–14 times larger than Moundville's. There are also indications that the residential population surrounding Cahokia, especially the upland Richland complex of communities, was probably multiethnic. The pluralistic nature of the population at Cahokia appears to be different from most other Mississippian polities in the heartland, a characteristic that distinguishes it from most chiefdoms. Elaborate mortuary rituals often considered to indicate social hierarchy also have been documented at Cahokia within Mound 72, a small ridge-topped mound that contained numerous staged internments, mass burials, and caches of grave goods (Fowler et al. 1999).

The Cahokian polity was closely associated with the Braden art style, which was likely the foundation for later Mississippian iconographic styles, such as the Hightower (Etowah), Hemphill (Moundville), and Craig (Spiro) styles. Moreover, iconographically charged objects may have perpetuated an ideology that promoted Cahokians as important mediators with cosmos. Such mediators would have been essential in enacting ritual renewal through green corn ceremonialism and renewing the new fire. For example, Pauketat and Emerson (1991) have argued that Ramey Incised pots served to legitimate chiefly authority in which comestibles were "redistributed" and elite ideas were diffused to regional nonelite (often) peripheral populations.

The Moundville site was the center of another large Mississippian political polity, probably a paramount chiefdom. It is located on a high terrace on the Black Warrior River in western Alabama. The site is composed of 32 mounds and a rectangular plaza. The mounds positioned around the plaza seem to have been paired. Knight (1998) has suggested that the spatial arrangement of the mound and plaza complexes at Moundville mirrored its social organization. Correspondingly, he has argued that these mounds were built and controlled by a number of politically and ceremonially integrated groups, possibly with a dualistic social system. There were also dense occupations at Moundville, especially soon after it was founded, but later the site was used primarily as a necropolis to bury the dead. In the broader region, there are also four smaller mound sites that are probably associated with Moundville. However, there is relatively little domestic debris around the mounds at these sites so they may not have been aggregated villages (Wilson et al. 2006).

There are, of course, other large important Mississippian mound centers, including Etowah in Georgia, Spiro in Oklahoma, and Kincaid in Illinois among others, as well as numerous smaller mound sites. In general, many of these Mississippian polities followed a similar developmental trajectory marked by an initial period of political consolidation and population aggregation. Later, when these Mississippian polities were declining, the population living at these mound centers dropped, and they were used increasingly as ceremonial centers. In certain cases, this ceremonial use focused on burying important deceased individuals with elaborate ritual objects, and these sites became essentially necropolises.

The influence of Mississippians extended out of the heartland into Florida and the Upper Midwest where cultural groups with many Mississippian traits and possibly ethnic connections have been identified, such as the Oneota groups of northern Illinois, Wisconsin, and Iowa, and the Fort Walton culture of northern Florida.

Within the heartland itself the Fort Ancient tradition was an important regional variation during the Late Prehistoric period. The Fort Ancient tradition developed in the central Ohio River drainage after around CE 1000. On the basis of highly similar ceramics, greater interaction occurred between Fort Ancient populations after CE 1450, but breakdown of the tradition occurred after approximately CE 1700 (Drooker and Cowan 2001). Fort Ancient groups produced shell-tempered ceramics that have some Mississippian stylistic elements and similarities. Their subsistence economy centered on maize and native cultigens but also included wild plants and animals. Fort Ancient settlements are primarily found in the floodplains, and they included nucleated villages after approximately CE 1100. Central plazas, large (possibly communal) structures, and stockades have been observed at Fort Ancient sites after CE 1200. Late Fort Ancient settlements of the Madisonville horizon sometimes became quite large villages. There are a number of SECC shell gorgets and other icons found at Fort Ancient sites that point toward interaction with Mississippian groups further south. Other artifacts, such as some Iroquoian-style pipes, point to relationships between Fort Ancient groups and communities further north (Drooker and Cowan 2001). Studies of grave goods suggest that there was little ascribed ranking among Fort Ancient populations, and archaeologists believe these people may have been organized into a tribal confederacy rather than a hierarchical chiefdom (Drooker and Cowan 2001).

Issues and Debates

Given the rich archaeological record for Woodland and Mississippian peoples of the heartland, it is not surprising that there are many substantive and theoretical debates among contemporary archaeologists studying these cultures. We have space to introduce only some of these issues in this entry. We briefly introduce some topics of debate in this section and organize these subjects into three broad areas of interest: (1) ecology and economics, (2) sociopolitical organization and interaction, and (3) ceremonialism, religion, and mortuary behavior. Each of these broad areas of interest has been stimulated by changing theoretical perspectives as heartland archaeologists moved from an initial focus on culture history to a processualist emphasis on adaptation and cultural evolution, and then incorporated aspects of the post-processualist critique by variously focusing on human agency, gender, material culture, and symbols.

Ecology and Economics

Interest in human–environment interactions has been significant since the beginning of North American archaeology. Initially debates often centered on the degree to which the environment shaped culture. For example, an issue was whether particular social forms including the presumably more sociopolitically complex societies of the heartland developed because of the relative richness of regional resources or as a result of historical forces and diffusion. Since the 1960s and 1970s, this debate has become less generalized, and more evidence for human use of environmental resources has made it possible to explore detailed patterning in subsistence and economy over time and across the heartland. Critiques of the processualist and adaptationist

perspective have not reduced interest in the variable ways in which humans have interacted with the environment. Instead, attention has been refocused on the complex social and ideological factors that affect human choices about resource use as well as on how humans, intentionally or unintentionally, shaped the landscapes in which they lived.

One key area of debate and research surrounds the development of indigenous agriculture. As previously discussed, several seed-bearing plants native to the Eastern Woodlands and adjacent areas that were first grown in the Archaic period also were cultivated by Woodland and Mississippian people in the heartland. Although the use of these plants became widespread, their role in local economies does appear to have varied. New dating evidence also calls into question the previous consensus that maize was gradually incorporated into heartland economies (Simon 2017). While intensification of maize agriculture does not occur before the Late Woodland or the Mississippian periods, variability in the timing and nature of its adoption and in the role of the hardier Northern flint variety seems evident, but is poorly understood.

A second, related topic of debate has to do with how the iconic Native American maize–bean–squash polyculture came into being. Maize and beans, the two principal tropical cultigens eventually adopted by heartland societies, have different histories with beans arriving only between CE 1200 and 1300 (Hart et al. 2002). Though well-known from ethnohistorical and ethnographic accounts, this polyculture was not developed in the heartland and other parts of the Eastern Woodlands until after this time. Thus, the diversity of agricultural systems developed by both Woodland and Mississippian societies has become clearer, as more data have been accumulated. Environmental, historical, economic, demographic, and ideological factors all may have influenced the specific nature of Woodland and Mississippian agricultural production and political economies.

Other questions have to do with the ways in which Woodland and Mississippian people enhanced the natural environment in order to acquire more food and raw materials. There has been debate about whether human agents intentionally disturbed particular environmental niches to promote the growth of certain oily and starchy seeds (Smith 2011). Certainly many actions of heartland peoples promoted the kinds of early successional habitat types that contain more food for humans. In the mature forests of the heartland, most of the biomass is trapped in forms such as cellulose that humans cannot digest. Disturbed habitats, old fields, and natural forest clearings and edges contain many more edible fruits, seeds, and shoots. These niches also attract important game species like the white-tailed deer, rabbits, and many birds. Garden hunting for these animals likely was practiced by Mississippian peoples. Some Woodland and Mississippian peoples likely cleared and burned the forest to create fields and gardens, but it also was accomplished as groups established and moved their villages. Thus, the growth and aggregation of Woodland and Mississippian populations disturbed more forest, and these actions favored mast-bearing trees like oak and hickory. These people probably also transplanted fruit-bearing trees to open areas within the forest and broadcast some native seed plants on river banks. Archaeologists are just beginning to realize the many ways that heartland peoples managed and structured the environments in which they lived.

Sociopolitical Organization and Interaction

Neoevolutionary ideas have had a major influence on archaeological conceptualizations of the Woodland and the Mississippian periods in the heartland. Early archaeologists tended to see both the Hopewell and Mississippian patterns as representing sociopolitically complex, ranked societies made possible by agricultural economies. Archaeologists started to recognize that the sociopolitical organization and economy of these societies varied more extensively as knowledge about their subsistence and settlement strategies accumulated. Today, Woodland peoples including the Hopewell usually are understood as tribal people, whose elaborate ceremonial life symbolized and reinforced kin groups, social identity, and cosmological beliefs. In contrast, Mississippians

have continued to be understood as internally differentiated chiefdom societies, and key debate centers on how power was distributed, how resources were controlled, and how ceremonial life symbolized religious belief.

One key debate of this type has been about the nature and size of Hopewell communities (e.g., Carr and Case 2005; Charles and Buikstra 2006; Byers and Wymer 2010). Although large Hopewell mound centers have long been known in Ohio, Illinois, and elsewhere, settlements often seem small and ephemeral in comparison, and domestic structures have not been well documented. Hopewell mound centers certainly do not contain large numbers of domestic structures, but instead were centers for ritual events that often involved the disposal of the dead. If Hopewell people did not live at these sites, where did they reside? While the settlements of the Illinois Hopewell may or may not have included large residential villages, as well as mound complexes and small hamlets, it does appear that residential sites were grouped into spatially integrated communities that probably linked related lineages and utilized distinct mound complexes (Carr and Case 2005). In Ohio, some researchers propose a dispersed sedentary community model in which single or sometimes multiple household units were dispersed across the landscape although they shared a corporate ritual space at mound centers that were periodically visited. Mound ceremonialism thus reinforced kinship-based identity and community that may not have been linked to spatial proximity. Other archaeologists question the duration of occupation or sedentary nature of Hopewell hamlets (Charles and Buikstra 2006). There also is related debate about how territorial Hopewell people were.

The nature and significance of exchange and interaction among Hopewell and other Middle Woodland people is a subject of active debate and research as well. As we have noted, there is considerable evidence for the exchange of Hopewell material culture and raw materials across the heartland and beyond during the Middle Woodland. This phenomenon was coined the Hopewell Interaction Sphere (and linked to both economic and religious interaction). Mound centers may have been nodes in elaborate regional trading networks as well as sacred places. However, interaction implies some level of cultural pluralism and the diversity in many ceramics or other aspects of material culture indicate the ethnic diversity of the people who participated in Hopewell ceremonialism. As data have accumulated, some researchers have even questioned the utility of terms like Adena and Hopewell that suggest cultural uniformity across the heartland (Clay 2014).

Another area of considerable debate is over the nature of Mississippian polities. Neoevolutionary concepts, especially Service's concept of a chiefdom characterized by hierarchical ranking, have been important concepts in modeling the nature of Mississippian societies even though these concepts were originally formulated for Polynesian societies (Peebles and Kus 1977). While not denying the sociopolitically complex nature of Mississippian societies, contemporary archaeologists have suggested that there was much more variability in how hierarchical and centralized power was in Mississippian polities (see Cobb 2003; Beck 2003). Pauketat (2007) has even suggested that the chiefdom model has limited our archaeological understanding of Mississippian culture by preventing an appreciation of cultural variability and human agency. Today, archaeologists debate the nature of leadership and power and also may view Mississippian societies as culturally plural (Blitz 2010).

Another topic of recent debate related to sociopolitical organization focuses on the nature and causes of conflict and warfare in Mississippian times. Despite popular characterizations of American Indians as peaceful, "noble savages," conflict and warfare have long histories in North America. Nevertheless in the heartland, warfare does not appear to have been more than periodic raiding and trophy taking until the Mississippian period (Milner 2007). The establishment of chiefdoms at this time can be linked to a shift from small-scale conflicts to large-scale internecine warfare between polities or within pluralistic polities, like the one centered at Cahokia. The widespread construction of stockades both within the heartland and elsewhere in the Eastern Woodlands is suggestive of intergroup conflict as well. However, there is debate about whether these conflicts

result mainly from resource stress resulting from larger and more aggregated human populations or from elites jockeying for power and legitimization of their authority (Dye 2009).

Ceremonialism, Religion, and Mortuary Behavior

A third area of recent debate is heartland ceremonialism, religion, and mortuary practices. The historical trajectory of research on these issues is quite different. Early work on these subjects sought to connect moundbuilding, burial practices, and certain objects to specific Native American communities and their beliefs. It included research on green corn ceremonialism, moundbuilding, ball games, and the Southeastern Ceremonial Complex (SECC). A few scholars explored these associations even when archaeological theories and thought shifted to more cross-cultural, scientific (processual) approaches.

Conversely, mortuary analyses became a privileged way of investigating the organization of heartland societies because distinctions among burials (e.g., grave goods and furniture) were believed to reflect their status. Thus, the internment of elaborate funerary objects and indeed elaborate mortuary programs themselves were viewed as indicating the deceased's high status (Saxe 1970). These approaches were applied throughout the heartland to analyze Woodland and Mississippian cemeteries. Archaeologists concluded that most Woodland cemeteries reflected status achieved through the lifetime of individuals. In contrast, differences among Mississippian burials were believed to reflect these societies' hierarchical organization.

Noteworthy studies include Peebles and Kus's (1977) analysis of burials from Moundville and Fowler et al. (1999) interpretation of the charnel facilities (including mass graves, caches, and elaborate internments) under Mound 72 at Cahokia. Both of these studies argued that Mississippian mortuary regimes reflected stratified chiefdoms. New analyses raise questions about these interpretations. For instance, the burials at Moundville are not contemporaneous and temporally significant patterns exist regarding how the dead were treated. Similarly, Emerson et al. (2016) have shown that the burials and charnel facilities under Mound 72 are not all contemporaneous, that some of the burials were not accurately aged and sexed, and that the funerary furniture associated with the (central) beaded burial was probably misinterpreted. Contemporary Mississippian scholars have also questioned a simplistic association between burial treatment and social organization, since mortuary ritual and spectacle can reinforce the structure of the larger community, enhance the power of leaders, and make connections with ancestors and cosmic forces (Sullivan and Mainfort 2012).

Another important issue is the construction of different mounds, enclosures, and other architectural features that correspond with astronomical events. It is clear that beginning in, at least, the Early and Middle Woodland periods, certain mounds and enclosures were constructed that aligned with solar, lunar, and/or other celestial events. In particular, the large Ohio Hopewell geometric enclosures and ritual architecture indicate a complex understanding of plane geometry, measurement, arithmetic, and observational astronomy closely tied to ritual practices. Mississippian people also constructed mounds and other architectural features that correspond to different astronomical alignments. While these astronomical alignments certainly were intertwined with the rituals and beliefs of Woodland and Mississippian peoples, the importance different celestial cycles and events played in their calendric systems has probably been underestimated. For example, it would make sense for dispersed Ohio Hopewell groups to time their rituals to correspond with different celestial events because these occurrences would have been visible in the day/night sky.

Finally, there has been a great deal of recent interest in Mississippian and Hopewell iconography. Iconographic approaches have addressed various issues through the formal analysis of heartland imagery, including the existence of different styles and workshops, as well as the patterning of specific motifs and themes and their referents. Yet linking pre-Columbian imagery with historically documented Native American religious beliefs, rituals, and cosmologies is challenging. Accordingly, debates exist about how feasible it is to trace the meaning of heartland

imagery through time and across cultural boundaries (e.g., disjunction).

Nevertheless, the objects associated with the Southeastern Ceremonial Complex have long fascinated archaeologists. They were once understood to represent a pan-Mississippian phenomenon, a religious cult, or prestige goods that circulated widely among the various groups. More recent iconographic studies have demonstrated the existence of regional styles. Specific studies of art styles and the meaning of specific motifs and themes are now being undertaken, which has led to increased discussion about Mississippian beliefs and cosmology (Reilly and Garber 2007).

Conclusion

The study of the Woodland and Mississippian peoples of the heartland in Eastern North America has been a major focus for North American archaeologists since the mid-nineteenth century. Today the Woodland period is considered to have encompassed the period from approximately 1000 BCE to CE 1000. The Woodland period is commonly broken into Early, Middle, and Late subperiods. The (Early to Middle Woodland) Adena and the Hopewell complexes stand out as particularly important cultural phenomena. After CE 1000, Mississippian polities of varying organization and complexity came into existence in the heartland with Early, Middle, and Late Missisisipipan subperiods also being recognized. Archaeologists have accumulated a great deal of evidence about Woodland and Mississippian people, which makes possible the discussion and debate of many significant methodological and theoretical topics. Nonetheless, a tremendous potential for future research on Woodland and Mississippian cultures in the heartland remains.

World Archaeological Congress (WAC)

Larry J. Zimmerman
Indiana University-Purdue University Indianapolis/Eiteljorg Museum, Indianapolis, IN, USA

Introduction

What eventually became the World Archaeological Congress emerged from what was initially planned as the 11th Congress of the International Union of Pre- and Protohistoric Sciences (IUPPS) to be held in Southampton, England, in September of 1986. The Southampton organizing committee had hoped to make the 11th Congress a more inclusionary meeting than previous Congresses. Mostly the IUPPS was organized by and for

Western European archaeologists, and while not specifically excluded from membership, archaeologists from non-Western nations had virtually no role in the organization. In response, several other organizations such as the Pan-African Congress and the International Congress of Americanists sought to alleviate the IUPPS's geographic biases. As well, Indigenous people, particularly from North America and Australia, had accelerated their demands for repatriation of the skeletal remains of their ancestors stored in archaeology laboratories and museums as well for a say in how their pasts were studied and represented. In response to these pressures, the 11th Congress organizers, particularly Peter J. Ucko, Chair of the Archaeology Department at Southampton University, made plans to assure the presence and participation of Indigenous people and archaeologists from a much wider range of countries than those usually at IUPPS World Congresses.

At the same time, growing violence associated with South Africa's apartheid policies had prompted organizations including the African National Congress, the National Union of Students, the Association of University Teachers, and several others to call for a ban of participation by South African and Namibian scholars in academic meetings. When the labor-dominated city government of Southampton announced that it would withhold financial support from the meeting unless IUPPS respected the ban, the local organizers agreed. However, the IUPPS and other archaeological organizations such as the Society for American Archaeology objected on the grounds of academic freedom for research and the free exchange of ideas. In early 1986, the IUPPS Secretary-General and International Executive Committee disavowed the Southampton meeting, which led to the withdrawal of many scholars from the meeting, but archaeologists from Eastern Europe, South America, Africa, and India supported the ban. The Southampton organizers agreed to proceed with the meeting as the World Archaeological Congress. The reasons that many either boycotted or chose to attend the meeting were complex (see Ucko 1987 and Gero 1999 for a detailed discussion of both events and attitudes), but what emerged was a very successful and exciting academic meeting, one that considered the usual scientific aspects of archaeology as well as openly exploring its political nature.

Approximately 850 people attended WAC-1 from 71 countries (more than twice the number present at the 10th IUPPS Congress in Mexico City). At the closing plenary of WAC-1, attendees resoundingly agreed that the World Congresses should continue, and the World Archaeological Congress emerged from that consensus. More than a quarter century has passed since the Southampton meeting. Since then WAC has become a vibrant organization, and given its origins in the shadow of apartheid, it is significant that WAC 4 was held in Cape Town, South Africa, with Nelson Mandela as its patron. Relationships with the IUPPS and the Society for American Archaeology have been mended, and while WAC is not the largest archaeological organization in the world, it certainly can lay claim to being the most active organization of archaeologists in terms of international influence.

Definition

WAC is both a quadrennial meeting and an organization. As a nongovernmental organization, the World Archaeological Congress is the only fully international and representative organization of practicing archaeologists (WAC 2010). WAC works to promote interest in the past in all areas of the world, exploring both the scientific and humanistic aspects of archaeology. As well, WAC has a specific mission to (1) promote professional training for disadvantaged nations and communities; (2) broaden public education, involving national and international communities in archaeological research; (3) develop archaeological practice so that it empowers Indigenous and minority stakeholders; (4) contribute to the conservation of archaeological sites threatened by looting, urban growth, tourism, development, or war; and (5) redress global inequities among archaeologists. WAC openly recognizes and explores the political role archaeology plays in

the construction of accounts of the past and the uses to which the accounts are put.

Governed by statutes that are regularly examined and revised (WAC 2009), WAC has 14 Regional Electoral Colleges designed to reflect geography and meant to foster development of regional networks that can facilitate study of the cultural heritage of each region. Members living in each region elect both a Senior and a Junior Representative to serve on the WAC Council. WAC also has an elected Executive with four officers (President, Vice-President, Secretary, and Treasurer) and those they appoint, usually the editor(s) of *Archaeologies*, the WAC journal, a Membership Secretary, a Student Representative, and the Coordinator of the major Congress meeting. Executive members communicate as needed by e-mail and often meet at WAC Inter-Congresses. Eight Indigenous Representatives, appointed by various Indigenous organizations, also serve as Council Members. The full Council tries to meet every 2 years but always meets as an Assembly during the quadrennial WAC Congress. The Assembly is WAC's principal policy-making body, elects officers, and determines the organization and location of future Congress meetings.

WAC Congresses generally have met every 4 years, but occasionally political or organizational issues at the selected venue have caused shifts in locations or slight delays. The initial Congress took place in England in 1986, followed by Venezuela (1990), India (1994), South Africa (1999), United States (2003), Ireland (2008), a 2013 Congress scheduled for Jordan, and WAC has offers to host the meeting well beyond 2013. Each Congress has produced about 10 published volumes of proceedings that comprise the One World Archaeology series. Historically, each Congress has at least partially supported the attendance of a large number of participants from traditionally underrepresented areas and groups, exactly those people who contribute to the essential diversity of WAC's purpose and who enhance the international scope of the conference.

Subject to approval by the Executive, WAC also sanctions Inter-Congresses, which are organized by members of the regional colleges, usually around a primary topic. Inter-Congresses have focused on topics as diverse as Heritage Management in East and South East Asia (Beijing, China 2011), Overcoming Structural Violence (Ramallah, West Bank 2009), and Kyosei-no-koukogaku: Coexistence in the Past – Dialogues in the Present (Osaka, Japan 2006). Since the first Inter-Congress on Archaeological Ethics and the Treatment of the Dead in 1989 (Vermillion, South Dakota USA), WAC has approved nearly 20 Inter-Congresses. WAC also sponsors Workshops and Symposia, usually in association with other national and international meetings.

WAC operates a Global Libraries Program, which provides publications to add to the archaeological literary collections of disadvantaged institutions. WAC publishers provide copies of all WAC publications, but many other print and digital materials come from members and philanthropic organizations. Archaeologists Without Borders supports archaeology education and training in countries where the development of archaeology has been economically difficult. Invited by host institutions, WAC members from different parts of the world provide advice, lectures and workshops, and other educational opportunities. WAC also operates an active listserv, accessible by both members and nonmembers, to foster exchange of information and opinion.

When WAC began it published *The World Archaeological Bulletin*, which ran through 2004. In 2005 WAC began publication of *Archaeologies: The Journal of the World Archaeological Congress*, now published in print and electronic versions by Springer. WAC also publishes the *Newsletter of the World Archaeological Congress*, now distributed only in electronic form. WAC also supports publication of two other peer-reviewed journals, *Arqueología Suramericana/Arqueologia Sul-Americana*, which is intended to promote and spread the production of archaeology and related disciplines in South America and the *Journal of Environment and Culture*, which provides a forum for debates on how culture and environment can be mutually complementary in Africa.

WAC has developed an active book publishing program, working with some of the world's finest archaeological publishers. The organization continues to produce its One World Archaeology series, numbering more than 60 volumes, growing by 10 or more volumes after each Congress. Most are edited volumes usually derived from Congress themes and sessions, but sometimes with additional papers solicited later. The Worlds of Archaeology series presents the global diversity of archaeology, foregrounding many different voices, particularly those silenced by colonial processes. The Archaeology and Indigenous Peoples series examines the current relationship and possibilities for collaboration between archaeologists and Indigenous peoples. The Research Handbooks in Archaeology provide comprehensive coverage and state of the art articles on key topics in the field. The Global Cultural Heritage Manuals seek to provide information for researchers planning archaeological or other heritage projects in a particular region, considering everything from environmental conditions to law. All royalties from all series publications go to support travel for disadvantaged scholars, students, and Indigenous people to attend WAC meetings.

The growth of the World Archaeological Congress has rarely been smooth. WAC makes a determined effort to keep membership fees very low and has a variable fee structure to support membership for Indigenous people, archaeologists from disadvantaged nations, retired and jobless archaeologists, and students. Although WAC receives substantial royalties from publications, those funds are directed toward travel support for the major Congresses. This has meant that WAC has always been dependent on volunteers, funds from host institutions, and gifts to support most operating costs. WAC has no professional administrative staff, and with the exception of occasional paid consultants and short-term, paid administrative support for meetings, it operates entirely with volunteers who serve roles in governance, editing and most translating, and on a variety of Task Forces and Standing Committees.

Because WAC has openly acknowledged and embraced the political side of archaeology, some archaeologists still tend to think of WAC as a political, rather than a scientific or scholarly, organization. For members, especially in Eurocentric countries, it is not uncommon to hear the charge that "WAC does politics, not archaeology." This has been especially the situation in the United States where archaeology has been epistemologically science-centered for decades. WAC certainly "does science" but maintains that all archaeology is political, yet such perceptions have worked to keep membership lower than it might be, usually about 1,200 members. Membership, however, has steadily grown as the journal has improved, as high-quality book series have appeared and as more archaeologists recognize that diversity serves the discipline well.

Key Issues/Current Debates/Future Directions

The core issues related to diversity within archaeology that led to the origin of WAC are still something of a problem. For example, WAC has worked very hard to select venues for its quadrennial Congresses and Inter-Congresses, which has rarely been easy. Some archaeologists argue that there is still a Eurocentric, economically advantaged country bias in venue selection, as well as a Northern Hemisphere bias (Shepherd and Haber 2011). Hosting a major international conference or even a smaller Inter-Congress is no simple undertaking financially or logistically. Given WAC's meager financial resources, the organization can be of little help with funding, although with several Congresses and nearly 20 Inter-Congresses, WAC can provide a lot of advice and logistical support. Financial and logistical issues for the host countries are one matter, but their archaeological, international, and internal political situations at the time also can cause problems. WAC 2 (1990), for example, was to have been in Colombia, but drug-based terrorist activities in the host city forced a shift to nearby Venezuela. WAC 3 (1994) in India proved difficult due to the destruction of the Ayodhya temple, which divided the Indian public and even the archaeological community, so much so that fights

broke out at the closing plenary. WAC 5 (2003) in Washington, DC, took place 2 years after the 9/11 terrorist acts, and the resulting security in the United States proved to be so paranoid and strict that many delegates could not get visas to enter the country. WAC 6 (2008) was initially planned for Jamaica, but last-minute economic issues forced a shift to Ireland where a national dispute over possible damage from highway construction to the important cultural landscape surrounding Tara spilled over into the meetings. In spite of these difficulties, all the meetings proved to be intellectually successful and very rewarding for attendees, so much so that many attendees to WAC meetings remark that they are "life-changing" experiences.

Even though WAC may sometimes be criticized for economic or geographic biases, other concerns actually stem from the substantial diversity that WAC does have. As might be expected, in an organization that embraces the political nature of archaeology, there are diverse opinions about how archaeology should be done and what policies and actions are ethical. Most such issues relate to WAC's interaction with non-archaeological entities such as the military or multinational corporations (Shepherd and Haber 2011; Smith 2011). At the simplest level the WAC Executive has been asked to intercede on behalf of particular issues within countries, usually on behalf of protection of important sites endangered by development activities, looting and sales of antiquities or human remains, allegations of ethical violations, or pending laws or policies regarding heritage. The Executive has sometimes done so but occasionally receives criticisms for engaging with the problem before it has adequate data or because it is seen as an extra-national entity without a right to be involved. Often the matters are international in scope. Shepherd and Haber (2011) have raised concerns about how WAC engages with multinational corporations that cause environmental and heritage damage as well as impinge on Indigenous lands, cultures, and rights. Before and at WAC 6 in Ireland, several WAC members challenged WAC's engagement with any military personnel or military-related activities, urging that no members of the military or archaeologists working with the military be allowed to present papers at the Congress. The WAC Executive has certainly struggled with many of these issues and has relied on the WAC Ethics Committee for advice about policies of engagement. Many questions get explored at sessions during the major Congresses and at some Inter-Congresses. Resolutions generated during the closing plenary sessions may be discussed and voted on, and if they are affirmed, they are passed along to the Executive for consideration and possible enactment as WAC policy, statute, or ethics codes.

WAC's diversity actually presents something of a structural contradiction. Diversity brings a wide range of opinion on almost every issue, and the need for fairness demands that those opinions be openly discussed. That makes decision-making slow and to some makes the organization seem cumbersome and conservative, perhaps even cowardly. Many members want WAC to be political and progressive, but were it to act decisively, it would risk being unfair or biased toward particular viewpoints. In spite of this conundrum, most archaeologists now recognize that archaeology is indeed political and the politics must be discussed openly; heritage issues of concern to Indigenous people and other descendant communities are now a regular part of archaeological consideration; archaeologists from economically disadvantaged and previously colonized nations are partners in the development of the discipline. Certainly issues and concerns remain, but WAC truly must be seen as a resounding success having moved well beyond the vision of Peter Ucko and the Southampton organizing committee.

World Archaeological Congress (WAC) and Cultural Heritage Management

Jordan Ralph
College of Humanities, Arts and Social Sciences, Flinders University, Adelaide, SA, Australia

Basic Information

> "The World Archaeological Congress is a non-governmental, not-for-profit organization and is the only representative world-wide body of practising archaeologists" (http://www.worldarchaeologicalcongress.org/about-wac).

The World Archaeological Congress (WAC) is dedicated to protecting, promoting, and preserving the cultural heritage of all cultures. WAC plays an active role in cultural heritage management by providing an international platform for researchers and Indigenous groups to unite, share knowledge, and enhance the protection of global cultural heritage.

Every 4 years, WAC hosts an international congress; archaeologists, members of First Nation groups, and Indigenous peoples from across the globe attend these congresses. Cultural heritage is a focus of all of these major conferences. Some 1,800 archaeologists attended the WAC-6 Congress in Dublin in 2008 and over 1,000 people attended WAC-7 at the Dead Sea in Jordan in 2013 (http://www.worldarchaeologicalcongress.org/events/congresses). WAC supported the attendance of over 230 participants from Indigenous and economically disadvantaged countries at WAC-6 and 440 people at WAC-7. This is part of a process of democratizing knowledge dissemination by scholars from around the world. WAC Congresses allow for the inception, intensification, and transferral of new ideas between participants and create an ever-strengthening, interconnected network of knowledge as a resource that can be used by current and future generations of researchers and stakeholders in cultural heritage.

WAC also holds smaller, themed inter-congresses in the area of cultural heritage. These have included *Indigenous People and Museums* (Indianapolis, USA, June 2011), *Archaeological Invisibility & Forgotten Knowledge: Ethnoarchaeology, Hunter-Gatherers, Ephemeral Cultural Aspects* (Lodz, Poland, September 2007), and *Threats to Archaeology: Its Importance, Its Values and Its Development* (Kingston, Jamaica, May 2007). The inter-congresses serve a similar purpose to the international congresses but focus on specialist discussions of a specific theme. Inter-congresses are held at shorter intervals than full Congresses, and there can be multiple inter-congresses in 1 year. These conferences, along with the many WAC publications, illustrate WAC's commitment to facilitating global dialogue on cultural heritage matters.

WAC's publications that focus on cultural heritage include the refereed journal, *Archaeologies*, which is published three times a year. The aim of *Archaeologies* is to make research and relevant issues accessible to a wider audience in a timely manner. WAC publishes several book series, including *One World Archaeology*, *Indigenous Archaeologies*, and the *Global Cultural Heritage Manual Series*. Contributors to these publications come from many backgrounds and countries. These WAC publications accelerate expansion of the archaeological literature and knowledge in cultural heritage.

Major Impact

WAC plays a proactive role in the cultural heritage management of Indigenous and First Nations peoples and indeed members from economically disadvantaged nations. WAC's Archaeologists without Borders and the Global Libraries Programs aim to overcome economic disparity in education and training and provide some necessary tools for archaeologists in economically disadvantaged nations as well as sharing knowledge from, and within, these nations. These initiatives, together with subsidized membership, further WAC's goal to make participation in global archaeology and cultural heritage management accessible to all peoples, to lessen economic and geographic barriers to the growth of knowledge in archaeology and cultural heritage.

WAC congresses, publications, and workshops facilitate Indigenous voice when such groups need international support and an avenue into mainstream media. Part of WAC's remit is to empower Indigenous and First Nation peoples' involvement in the heritage management of their culture. WAC does this by providing sponsorship for Indigenous people to attend its events and by providing support for members from economically disadvantaged countries. WAC's discussion list server supplies members with a direct line of communication to heritage experts seeking to undertake ethical best practice procedures in heritage research and management when working with Indigenous groups.

WAC provides a means to protect culturally sensitive heritage through its codes of ethics: the First Code of Ethics (1990), The Vermillion Accord on Human Remains (1989), and The Tamaki Makau-rau Accord on the Display of Human Remains and Sacred Objects (2006) (http://www.worldarchaeologicalcongress.org/about-wac/codes-of-ethics). According to these codes, consultation with relevant communities must be sought, and respect must be taken when working with sensitive cultural matters. While the codes are not legally binding, WAC members have a professional and ethical obligation to abide by them.

WAC produces an informal newsletter several times a year that updates members about issues in global heritage and instigates dialogue between the executive and members to deal with the issues effectively. The importance of this dialogue surfaced in early 2011, which was a tumultuous period for heritage protection. The April newsletter outlined the threats to Ugandan, Bangladeshi, Egyptian, and Libyan cultural heritage due to development and military action and declared WAC's opposition to these events (http://www.worldarchaeologicalcongress.org/images/pdfs/enews_37.pdf). As outlined in the newsletter, WAC continues to monitor these events and lobby the relevant governing bodies to protect their sites.

WAC plays an integral role in expanding the archaeological discipline and ensuring that all of its global, interconnected members undertake cultural heritage management ethically and that the cultural heritage of all peoples and all nations can be protected equally.

World Archaeological Congress (WAC): First Code of Ethics

Larry J. Zimmerman
Indiana University-Purdue University Indianapolis/Eiteljorg Museum, Indianapolis, IN, USA

Introduction

Following on the success of the 1986 World Archaeological Congress (WAC) in Southampton (UK) in 1989, the organization held its first Inter-Congress on the topic Archaeological Ethics and the Treatment of the Dead in Vermillion, South Dakota (USA). Attendees at that meeting passed the Vermillion Accord, a six-clause statement recognizing the rights, obligations, and concerns of Indigenous people and scientists relating to ethical treatment of the dead. Several Indigenous people who attended that meeting went to the WAC II meeting in Barquesimeto, Venezuela, the following year. A Maori representative, Hirini Matunga, organized a small session of other Indigenous attendees and one archaeological advisor to discuss a possible code of ethics that would move beyond repatriation issues into broader concerns about the rights of Indigenous people to have a voice in how their own heritage is studied or represented.

Matunga presented a draft document to the group asking their concerns about what they wanted from their interaction with archaeologists and other heritage scholars, how they could best assure that this might happen, and what behaviors they expected from archaeologists. The two sections of the code reflect many of their concerns. The section entitled "Principles to Abide By" primarily focuses on acknowledgment by WAC members that Indigenous people have primacy over all aspects of their heritage and that members should seek to collaborate with those whose heritage they study, including them in everything from setting research agendas to funding. The second section, "Rules to Adhere To," is a more precise set of expected behaviors of members that recognize the need for fully informed consent, clearly stated boundaries for research, obligations related to reporting of findings, and long-term treatment and protection of Indigenous heritage.

Committee members expressed concern about whether the language of the draft code would be too strong for the WAC Executive and Council to accept, but when the Indigenous Representatives to the Council offered it the next day, Executive and Council easily adopted the *First Code of Ethics: Members' Obligations to Indigenous Peoples* (Zimmerman and Bruguier 1994).

Definition

Although it is usually just called the WAC Code of Ethics, the official name of the document is *The World Archaeological Congress First Code of Ethics: Members' Obligations to Indigenous Peoples*. The title recognizes that this listing of principles and behaviors specifically addresses only concerns about Indigenous heritage and that it is not a full set of ethical obligations of archaeologists to all aspects of heritage. The idea that it is a *first* code recognizes that ethics are constantly changing and will eventually need alteration as conditions shift. The code is as follows (World Archaeological Congress (WAC) n.d.-a):

Principles to Abide By

Members agree that they have obligations to indigenous peoples and that they shall abide by the following principles:

1. To acknowledge the importance of indigenous cultural heritage, including sites, places, objects, artefacts, human remains, to the survival of indigenous cultures.
2. To acknowledge the importance of protecting indigenous cultural heritage to the well-being of indigenous peoples.

3. To acknowledge the special importance of indigenous ancestral human remains, and sites containing and/or associated with such remains, to indigenous peoples.
4. To acknowledge that the important relationship between indigenous peoples and their cultural heritage exists irrespective of legal ownership.
5. To acknowledge that the indigenous cultural heritage rightfully belongs to the indigenous descendants of that heritage.
6. To acknowledge and recognise indigenous methodologies for interpreting, curating, managing, and protecting indigenous cultural heritage.
7. To establish equitable partnerships and relationships between Members and indigenous peoples whose cultural heritage is being investigated.
8. To seek, whenever possible, representation of indigenous peoples in agencies funding or authorising research to be certain their view is considered as critically important in setting research standards, questions, priorities, and goals.

Rules to Adhere to

Members agree that they will adhere to the following rules prior to, during and after their investigations:

1. Prior to conducting any investigation and/or examination, Members shall with rigorous endeavor seek to define the indigenous peoples whose cultural heritage is the subject of investigation.
2. Members shall negotiate with and obtain the informed consent of representatives authorised by the indigenous peoples whose cultural heritage is the subject of investigation.
3. Members shall ensure that the authorised representatives of the indigenous peoples whose culture is being investigated are kept informed during all stages of the investigation.
4. Members shall ensure that the results of their work are presented with deference and respect to the identified indigenous peoples.
5. Members shall not interfere with and/or remove human remains of indigenous peoples with the express consent of those concerned.
6. Members shall not interfere with and/or remove artefacts or objects of special cultural significance, as defined by associated indigenous peoples, without their express consent.
7. Members shall recognise their obligation to employ and/or train indigenous peoples in proper techniques as part of their projects, and utilise indigenous peoples to monitor the projects.

Key Issues/Current Debates/Future Directions/Examples

Soon after the WAC Executive and Council passed the code, several other organizations including the Australian Archaeological Association and the Canadian Archaeological Association adopted similar codes, using the WAC code as a model. To date the code has remained unaltered, but was extended when the WAC Council adopted The Tamaki Makau-rau Accord on the Display of Human Remains and Sacred Objects (World Archaeological Congress (WAC) n.d.-b). The WAC Standing Committee on Ethics is charged with monitoring WAC ethics and has begun development of a general code of ethics as well as an international code of ethics. In a 2007 meeting, the committee agreed to a set of core values and processes to be used to evaluate future consideration of WAC ethics. They also prepared a draft general ethics code that will remain under discussion for the foreseeable future (World Archaeological Congress (WAC) n.d.-c).

World Heritage and Human Rights

Helaine Silverman
Department of Anthropology, University of Illinois at Urbana-Champaign, Urbana, IL, USA

Introduction

In a new book series called "Critical Perspectives on Cultural Heritage," editor Beverly Butler describes an intellectual program whose goal is to disrupt Eurocentric cultural heritage theory and practice, propose "alternative intellectual, moral-ethical, and also grounded concerns," and center "cultural heritage discourse within a wider concern for the preservation of human dignity and human justice and to use these alternative discourses as a resource for future action in terms of creating a proactive (rather than reactive), responsive and just future for a new critical cultural heritage studies" (Butler 2007). Critical heritage scholars are deeply concerned about social, economic, and political inequities worldwide. It is not surprising, then, that human rights have become an important focus in this domain of the cultural heritage field as well as among progressive archaeologists. Nor is this interest new, although interest in it has lagged until recently. In 1968 – on the twentieth anniversary of UNESCO's "Universal Declaration of Human Rights" – UNESCO held a meeting on "Cultural Rights as Human Rights" in which experts discussed community or group rights (Aoyagi 1970), the notion of universal culture and its engagement with national culture (N'Daw 1970), elite and majority culture (Debesa 1970), and other topics now current (such as the role of mass media and access to science and technology) (UNESCO 1970). Unfortunately, UNESCO's 1970 monograph on this subject went largely unnoticed, although the field of heritage studies was exploding onto the scene in the 1980s and 1990s, resulting in the twenty-first century bounty we see today.

Definition

Defining human rights is the crux of the issue. They are a particular category of rights whose definition has varied widely over time. The philosophical framework for the contemporary notion of human rights emerged out of the Enlightenment. As currently conceived, at least in the West, they are best defined by the United Nations 1948 Universal Declaration of Human Rights. Since promulgation of that charter, there have been further declarations. The human rights we speak about today are those recognized in international law rather than (or more than) being predicated upon earlier moral or philosophical premises. The reader is directed to the various international documents.

Key Issues

Cowan et al.'s (2001) *Culture and Rights* and UNESCO's promulgation of the 2001 "Universal Declaration on Cultural Diversity" and 2003 "Convention for the Safeguarding of the Intangible Cultural Heritage" revived interest in the topic of human rights. In March 2006, *American Anthropologist* published a themed set of papers dealing with human rights (Goodale 2006). Independently and at the same moment, the Collaborative for Cultural Heritage Management and Policy (CHAMP) at the University of Illinois (called at that time Collaborative for Cultural Heritage and Museum Practices) hosted its first annual international conference and chose "cultural heritage and human rights" as the topic for discussion (Silverman and Ruggles 2007). In 2007, ICOMOS-Australia, Deakin University, and the University of Ulster held two important research workshops at which multiple rights were debated (Langfield et al. 2010). In 2010, the Princess Maha Chakri Sirindhorn Anthropology Centre in Bangkok launched a national culture and rights project in Thailand. In February 2011, the Office of the United Nations High Commissioner on Human Rights (in UNESCO's Geneva office) convened a dozen cultural heritage experts to consider the issue of access to cultural heritage as a human right. A few weeks later, ICOMOS-Norway held a meeting to promote a rights-based approach to cultural heritage (see Ekern et al. 2012).

Clearly, we are witnessing the emergence of an important new paradigm within the field of critical heritage studies. But its consensual form remains to be worked out. What do we actually mean by human rights applied to cultural heritage? This is a temporally shifting definitional terrain as some cultural rights once defended have come to be criticized and vice versa. Indeed, what is "culture" now that it has been unmoored from its antiquated conceptualization of bounded entity?

Fundamentally, the linkage of cultural rights and human rights must signify social, political, and economic equity in the vibrantly creative embodied lives of actors at the local level of stakeholders and communities. Therefore, can and should cultural rights and human rights be universalized as encompassed by UNESCO's various declarations – beyond the idealistic notion of all of humankind being enriched by the enjoyment of everyone's cultural heritage ("outstanding universal value")? Cowan (2006) worries appropriately about a hegemonic rights framework. William Logan, who holds the UNESCO Chair at Deakin University, cogently identifies "the clash between universalism and cultural relativism" and sanguinely recognizes the pragmatic need to negotiate between absolutism in human rights and "broader community, regional and national interests, and, indeed, between various interests within the same local community" (2007: 50). Elazar Barkan is pessimistic about the ability of human rights scholars to elaborate a theory of "group rights" that can withstand the reality of "people everywhere [who] hold to cultural and political beliefs that they see essential to their own identity and culture, yet that are at the same time offensive, at times violently so, to others, both members of the groups themselves, and outsiders" (2007: 199). My position is that we must be very careful not to diminish the concept and advocacy of vital human rights by uncritically and automatically placing cultural rights on the

same plane. Human rights such as: life itself without fear of intimidation or physical abuse by the state or its agents; adequate food and health care; freedom of religious practice (or not to practice religion); group expression of cultural traditions (and the right to leave that tradition); freedom of political expression; unfettered mobility; gender equality. Not all cultural rights rise to the level of these human rights. Indeed, some cultural rights as locally practiced might be argued to abrogate human rights. The challenge is to defend those cultural rights that are human rights – but who decides? and how? – without provoking disastrous resistance by oppositional forces. Much work remains to be done on cultural rights, human rights, and heritage. The issue should not be abandoned because of its complexities. The field can advance by interrogating the concepts and improving the methods used to investigate these problems and, especially, by deploying ethnographically grounded studies of culture and rights that are "undertaken in a theoretically informed, reflexive and critical way" (Cowan 2006: 21).

Kirshenblatt-Gimblett has recognized the fraught issue of proprietary rights and cultural rights (1998: 65), a topic which has grown in importance. Concerning some sites already on the prestigious World Heritage List and others awaiting consideration by UNESCO's World Heritage Committee, there is a recurring problem of property rights for those who reside (especially if there is legal title) on land that lies within the officially delimited borders of the site. Some governments, such as Indonesia and Thailand, have removed settlements in their process of implementing a site management plan and opening of a site to increased tourism through the World Heritage Site moniker. Is residential tenancy a human right? Other interesting cases involve what a national heritage organization considers to be appropriate and inappropriate use of a site by local people. Do they have free (no entry fee required) access (availability at any time) to a site with which they have coexisted for generations? Are local stakeholders allowed to perform ceremonies on sites that they regard as important? Are these cultural rights or human rights?

A particular contribution of the international lawyer Rosemary Coombe is her recognition of the importance of governmentality in cultural heritage and her explanation of its object and instrument nature. Just as anthropologists comfortably speak of social constructivism, which was a paradigm shift only a generation ago, so now we must understand legal constructivism: "Identities do not exist before the law but are forged in relation to law" (Coombe 2010). The legal, social, and other technologies by which law is deployed generate and constrain opportunity, bringing this perspective into alignment with anthropologists' and archaeologists' greater familiarity with theories of agency, practice, and materiality.

The work of another international lawyer, Yvonne Donders (2008, 2009, 2010), in the field of social and cultural rights, human rights and cultural diversity, and human rights and development relates to the elaboration of the content, nature of obligations, state of implementation, indicators, and justiciability of economic, social, and cultural rights (see also Vrdoljak 2009, 2010). Lawyer Jane Anderson (2009) is especially concerned with philosophical and practical problems for intellectual property law and the protection of indigenous/traditional knowledge and cultural heritage.

Rights are becoming a major concern in the critical heritage field: rights *to, in*, and *as* heritage (Smith et al. in preparation). Here there is a great and necessary opportunity for heritage scholars to analyze, theorize, and recommend policy. The problem of a "universal validity of the language of rights" (Nussbaum 1998: 77) is readily translatable to debates about World Heritage under today's conditions of globalization, frequent inter-ethnic conflict, internal political unrest, and the tension between local/national identity and the constitution of world citizenship.

Also related to the issue of rights is the issue of peace. Logan (2010) eloquently propounds the use of heritage conservation to strengthen the defenses of peace, following the Preamble to UNESCO's 1945 Constitution and arguing against the politicization of the World Heritage List program (see also *The Economist* 2010;

Silverman 2011). Logan (2010) and Silverman (2011) share a belief in the value of transnational or transborder/transboundary inscriptions for mitigating conflict.

Human rights and cultural rights are complicated by UNESCO's World Heritage framework. Barbara Kirshenblatt-Gimblett precisely recognizes the "fundamental contradiction... between [UNESCO's] celebration of diversity, on the one hand, and [its] application of a universal standard" (2006: 187). Clearly, human rights will remain an important topic in heritage studies and heritage practice.

World Heritage Education, Training, and Capacity Building

William S. Logan
Cultural Heritage Centre for Asia and the Pacific, Deakin University, Melbourne, VIC, Australia

Introduction

Since the 1990s, many universities have launched Heritage studies programs, seven being listed on the UNESCO web site as having specialized in the study of World Heritage issues (UNESCO n.d.-a). Other universities include World Heritage alongside studies that are more focused on heritage at the national and local levels. UNESCO, the World Heritage Committee, and its secretariat, the World Heritage Center, have taken a number of initiatives to encourage universities to support its World Heritage mission, including recently encouraging the development of a new set of Category Two Centers (C2Cs).

Definition

At the heart of the ongoing debates about the role of universities and particularly about the C2Cs is the important distinction between "education" and "training." In simple terms, university education has breadth and depth of teaching based on research and analysis. Training, by contrast, is narrower in focus, shorter in program length, and more directed at meeting the specific needs of employer or special interest groups. A third term – capacity building – is commonly used which also focuses on the needs of heritage protection agencies. It embraces education and training but goes beyond both to strengthen institutions, communities, and networks in other ways (UNESCO and Kingdom of Bahrain Ministry of Culture 2011: 3).

Historical Background

The UNESCO World Heritage Convention 1972 was radical in its time in envisaging heritage as both natural and cultural and bringing the two together into a single normative statement and protective system. In the ensuing 40 years, both the community and professional views of what constitutes cultural heritage have broadened in many countries around the world. Educational programs have responded to this broadening conception of heritage and its value for contemporary society. Several important shifts can be discerned.

Moving from a mid-twentieth century focus on iconic monuments and archaeological sites, the criteria adopted for evaluating cultural nominations to the World Heritage List encompassed values that enabled the inscription of a wider range of places, such as vernacular building ensembles, historic towns and villages, and designed parks and gardens. In 1993, cultural landscapes and their associative values were added, while the last decade has seen a greater emphasis on the intangible values of places and debate about the addition of historic urban landscapes.

Another major trend has seen heritage discourse and practice move from a narrowly

technical focus to a more ethics-based approach. The World Heritage system has moved to a values-based approach to managing heritage places, and there has been an increased weight put on associative values, especially of indigenous communities. Questions about "Whose heritage?" and "In whose interest is a place being inscribed?" have been given higher priority, as, too, is the development of more inclusive heritage registers.

The global debates have led to the recognition that wide variations exist in the way heritage is understood from one world region to another and from one culture to another and that variation is part of the world's rich and creative cultural diversity. The Nara Conference on Authenticity in November 1994 had a major impact on heritage conservation theory and practice, concluding as it did that the ways of conserving heritage should be in accord with local ways of understanding heritage. This widening is seen in the debates about philosophy and practice in the key global organizations – UNESCO, ICOMOS, ICOM, ICCROM, and IUCN – and is reflected in the programs taught and the research undertaken in educational and training institutions at the national and global levels.

Educational Responses

Initially education and training providers responded to the global conservation effort spearheaded by UNESCO by creating a series of specialist courses, some dealing with the conservation of monuments and sites and drawing heavily on the disciplines of archaeology and architecture, others focusing on science- and laboratory-based materials conservation, and yet others on museology or public history (Logan 2010). In the 1970s and 1980s, ICCROM in Rome and the University of York in England were key training institutions. During the 1980s and 1990s, other universities moved into the heritage field, and courses were developed that, in relation to heritage places, shifted from technical restoration to focus on broader planning and management issues, often connected to economic development through tourism.

Within the last 15 years, the increasingly holistic conception of heritage has led to new batch of courses drawing together at least heritage places and museum studies and beginning to focus on intangible heritage and traditional knowledge systems. In some countries such as the United Kingdom, Australia, and, more recently, the United States, "heritage studies" has emerged as a new interdisciplinary area in its own right bringing together history and geography, architecture and archaeology, economics and town planning, anthropology, ethnology and folklore studies, art history, and museum studies and with strong emphases on the interconnections between philosophy, theory, and practice.

UNESCO Engagement with Education and Training

Article 5 of the World Heritage Convention 1972 calls on States Parties to "foster the establishment or development of national or regional centres for training in the protection, conservation and presentation of the cultural and natural heritage and to encourage scientific research in this field." Despite this unambiguous statement, little was initially done within the UNESCO system to link heritage and education. Since the 1990s, there has been a more concerted effort by the World Heritage Center to influence curricula and bring students and teaching staff in schools and universities into actively supporting UNESCO's World Heritage program. For a discussion of initiatives taken at the school level, see Logan (2012a).

UNESCO's connection with universities has a long and honorable history, dating back to the appointment of former Oxford scholar, Julian Huxley, as its first director in 1946 and continuing with the regular commissioning of university scholars such as Claude Lévi-Strauss to write key reports. In 1991 UNESCO's General Conference decided to create and set up a network with the UNITWIN program under which universities agreed to collaborate, usually across the North/South divide, and the appointment of UNESCO Chairs (UNESCO n.d.-b). The aim of both components is to facilitate knowledge and skills transfer and institutional capacity building through

training, research, information sharing, and outreach activities in UNESCO's major program areas of education, natural sciences, social and human sciences, culture, and communication and information. As of 31 May 2011, there were 715 UNESCO Chairs. Of these, 23 are designated to the field of cultural heritage, although several of the earlier ones created in the 1990s appear to now be defunct (UNESCO n.d.-c). There are no Chairs in the natural sciences focusing on natural heritage.

Apart from a 10th anniversary meeting held at UNESCO Paris headquarters in November 2002, there has been little linkage between the various UNITWIN programs or the UNESCO Chairs. A number of other networks have tried to fill this gap but have also been less successful than hoped. The Forum UNESCO: University and Heritage (FUUH) network was established by UNESCO in 1995, initially under the management of the Valencia Polytechnic University in Spain but now jointly managed by that university and the World Heritage Center. The FUUH mission is broad and emphasizes supporting UNESCO action in favor of cultural and natural heritage protection, enhancement, and conservation. FUUH is an informal network whose main collaborative activity has been the annual, now biennial international conferences, and it has run in 13 university locations across the world (FUUH n.d.).

Other networks have been established at a regional level. For instance, in 2001, ICCROM joined forces with UNESCO's Office of the Regional Advisor for Culture in Asia and the Pacific based in Bangkok to form the Asian Academy of Heritage Management (AAHM). This is a network of institutions, mostly universities, that offers professional training in the field of cultural heritage management (UNESCO Bangkok, AAHM n.d.). Such training is seen to be critically important given the Asia-Pacific context of rapid environmental degradation, urban infrastructure development, and mass tourism. Since 2008, the network has become more self-governing, and its principal activity has been a major regional conference held every 18 months or 2 years.

Key Issues/Current Debates

While reference is conventionally made now to the conservation of cultural heritage as being a multidisciplinary activity requiring a holistic approach, both in management and education, in reality many obstacles make this difficult to achieve. It is regrettable that the definition and management of heritage is divided between UNESCO conventions and programs and in administrative arrangements at the global level and commonly, too, at the national level. Faculty divisions within universities continue to make it difficult to educate students across the range of disciplines needed to practice heritage conservation in a more holistic way, even to deal with natural and cultural values under the World Heritage Convention let alone working with intangible values, cultural expressions, and heritage representation in museums or to deal with growing concerns about heritage sustainability, environmental degradation, and the potential impacts of climate change.

Increasingly, however, heritage is seen not simply as a reflection of the world's rich and creative diversity but as the very underpinning of the cultural identity of people, and its maintenance is considered a basic human right. In other words, heritage conservation can no longer be seen just as a technical issue; it always involves fundamental philosophical and ethical questions, and these must be incorporated into heritage courses in universities: Why are we doing it? Who for? Who said? Are the local people whose heritage is being "protected" involved? How does it fit with other human rights? How does it fit with sustainability?

This shift has also been reflected in teaching and research in a number of university courses where heritage is understood as being produced through sociopolitical processes reflecting society's power structures. The close link between heritage and identity is recognized, as is the link between official heritage definitions and nation building and the misuse of "heritage" in some countries to reinforce the power of political elites and dominant ethnic groups. This means that while there remains a very clear need to produce graduates with practical architectural and

archaeological conservation expertise and heritage planning and management skills, the social sciences can add skills for analyzing the social, political, and economic context and for negotiating heritage conservation outcomes in situations where the identification, evaluation, and interpretation of heritage items is contested between various groups within the community.

This shift toward a more critical approach to heritage practice encourages scholars and practitioners to consider the human rights implications of conservation interventions and to devise ways in which local people, including indigenous peoples and ethnic minorities in particular, can be empowered to play a meaningful role in determining how their heritage is identified and managed. This ties in closely with the work being done by Ms. Farida Shaheed, Independent Expert at the UN Human Rights Commission in Geneva, who focused in 2011 on access to and enjoyment of cultural heritage as a cultural right (UNHRC 2011). It also resonates with efforts by the Advisory Bodies, notably the IUCN and ICOMOS, to move the World Heritage system toward a rights-based approach to site management. This new approach has already encouraged a rich stream of research in universities, and a number of books are now available that deal with the links between cultural diversity, heritage, and human rights (see, for instance, Silverman and Ruggles 2007; Langfield et al. 2010; Ekern et al. 2012).

International Perspectives

World Heritage education appears to have started moving in two directions – toward Critical Heritage Studies on the one hand, but toward a greater emphasis on skills training designed to meet the World Heritage system's specific needs on the other hand. In a carefully managed education system, both of these approaches should coexist so that students and researchers are able to ground theory in an understanding of practice. The signs are, however, that we are moving toward a dual system based on conflicting rather than complementary approaches.

In a sense, the division is occurring as a result of wider problems in the World Heritage system, especially the proliferation of inscribed places with severe management and sustainability issues. There are now 35 properties on the World Heritage in Danger List, and a further 135 were subject to close scrutiny in 2011 by the World Heritage Committee (UNESCO World Heritage Committee 2011). The World Heritage Committee's attempt to contain the problem through its "state of conservation" and periodic reporting mechanisms is not sufficient. There is a sense among some in UNESCO's cultural sector that there is a need for training that is more focused on meeting the specific demands of World Heritage sites.

Reemphasizing Skills Training

The World Heritage Committee called on the advisory bodies to revise its 2001 training strategy. Moving beyond training to cover institutional capacity building more widely, this new strategy was presented to the Committee at its 35th session in 2011. There had been some small representation of the UNESCO Chairs in the drafting sessions as well as an increasingly large participation by the Category 2 Centers. These centers, while not legally part of UNESCO, are associated with it by way of formal arrangements approved by UNESCO's General Conference. There are now 20 such culture-related centers of which six focus on World Heritage. Many States Parties are keen to establish a C2C, which is in line with their responsibilities under the Convention, but they must guarantee funding, possess staff with sufficient experience, and, perhaps most importantly, have a genuine commitment to making the C2C function effectively.

The majority of strongest universities in the heritage field will be outside the "Category 2 family" that is being created. There is a concern that the C2Cs will be perceived as having UNESCO's imprimatur but may not attain the same standards of teaching and research. The situation is exacerbated by confusion between the notions of education and training (Logan 2010). These are two different processes and can involve different agencies, universities focusing more on the

former although also providing training while professional bodies, government departments, and other agencies focus on training. University education is broad, questioning, liberating, and improving. With regard to World Heritage, university teachers are not trainers seeking merely to serve the needs of the World Heritage system. Of course there is a necessity to provide such technical expertise, but they have also to engage students in the larger philosophical concerns, to inculcate in them an appreciation of ethical responsibility, and to encourage critical analysis and debate.

Critical Heritage Studies

Critical Heritage Studies also takes the stance that heritage is not simply a reflection of the world's rich and creative diversity but is the very foundation of the cultural identity of people, and hence, its maintenance is basic human right. Again this means that heritage conservation can no longer be seen merely as a technical issue but needs to be seen in an ethical context; indeed, when talking of World Heritage, conservation should be seen more clearly as a tool for attaining the ethical mission set by UNESCO in its Constitution and other statements. An Association of Critical Heritage Studies has been established, and an inaugural conference was held in June 2012 at the University of Gothenburg, Sweden.

Future Directions

It is quite clear that growth of World Heritage system requires new responses, probably including a realignment away from serving the political and economic interests of the States Parties and toward the original UNESCO mission (Logan 2012b: 125–7). It is perhaps unfortunate that, given the increasingly difficult situation in which UNESCO's flagship World Heritage program finds itself, World Heritage education and training seems to be moving toward a dual system comprising C2Cs and the rest. It also be seen as running against the advice of the Independent External Evaluation of UNESCO when it recommended five strategic directions, the fifth being to develop a partnership strategy that included renewing, not scaling down, links with and between institutes, programs, universities, and centers of excellence that can improve UNESCO's performance (UNESCO Executive Board 2010: 11).

There is currently a sense of dismay in some universities. It is likely that Critical Heritage Studies will expand in the non-C2C universities and possibly assume a more questioning stance toward UNESCO and its World Heritage program. Other institutions may also be affected. The AAHM, for example, will no longer be in line with UNESCO's approach. ICCROM has already begun adjusting. The UNESCO Chairs in the cultural heritage field are likely to be brought under the direct control of the World Heritage Center, if they survive at all. The encouragement of a new batch of C2Cs may in some parts of the world draw students away from existing university courses, making them unviable. This is a risky experiment. It is too soon to know the consequences, but the collateral damage could be high.

World Heritage Journals

Alexander A. Bauer
Department of Anthropology, Queens College, CUNY, Flushing, NY, USA

Brief Definition of the Topic

Given the interdisciplinary and global reach of "heritage" in academic, professional, and community contexts, it should come as little surprise that journals that deal with the topic represent a great variety of subject matters and perspectives. Indeed, journals that include "heritage" in their title may just as likely be focused on conservation science as tourism, subjects that seem at first quite distant but are connected by their shared concerns with authenticity and preservation. As attention to heritage has grown over the past half century, in large part intertwined with the founding and expanded reach of the United Nations Educational, Scientific, and Cultural Organization (UNESCO) and other international bodies such as ICOMOS, so the number of journals devoted to heritage issues has increased. What follows is a summary of these publications, both those which are exclusively devoted to heritage (along its various dimensions) as well as those whose primary focus is elsewhere but nevertheless publishes a good deal of material important to the study of heritage.

Early Journals

Any review of the history of world heritage journals must begin by acknowledging the important role played by a more traditional "archaeology" journal, the *Journal of Field Archaeology*, founded in 1974 largely by faculty at Boston University's Department of Archaeology. Long before any other journals were focused on heritage issues, the *JFA* included from its outset a regular section called "The Antiquities Trade," whose aim was to "provide a forum for commentary on the illicit traffic in antiquities" (Wiseman 1974: 1). This feature remained an important part of *JFA* until 1993 and was revived in 2005 under the editorship of Morag Kersel and Christina Luke. In 1977, the *JFA*

established a second section entitled "Preservation and Rescue," under the editorship of Thomas F. King, which was a regular feature until 1982.

Several national and international organizations also published journals that included content on heritage preservation and policy. Upon their founding in 1948, UNESCO published *Museum International* and ICOM published *ICOM News*, magazines that regularly include articles on heritage issues. In 1978, the U.S. National Park Service began publishing its *CRM Bulletin*, which then became the more broadly construed *CRM Journal* in 2003.

It was not until the early 1990s, however, that journals devoted entirely to heritage issues were founded. In 1991, the *International Journal of Cultural Property* began publication, aimed at being an interdisciplinary law and policy journal on cultural property and heritage disputes. In 1994, the *International Journal of Heritage Studies* began publication, mainly on issues of heritage preservation and tourism. These were followed by *Art, Antiquity, and the Law* (1996); *Culture without Context* (1997–2006); and the *IFAR Journal* (1998), all focused on art and antiquities trade issues.

Recent Expansion of Heritage Journals

Since 2000, the number of journals focused on world heritage has greatly expanded to deal with the many different dimensions of the subject. There are now journals that focus on problems of conservation (*Journal of Cultural Heritage* [2000], *Conservation Science in Cultural Heritage* [2001]), tourism (*PASOS: Journal of Tourism and Cultural Heritage* [2003, e-journal], *Journal of Heritage Tourism* [2006]), intangible heritage (*International Journal of Intangible Heritage* [2006]), architecture and the built environment (*International Journal of Architectural Heritage* [2007]), and digital heritage (*ACM Journal on Computing and Cultural Heritage* [2008], *International Journal of Heritage in the Digital Era* [2012]). Finally, two recent journals have been founded that focus on the larger context of heritage in contemporary social life, *Heritage and Society* (founded in 2008 as *Heritage Management*) and the *Journal of Cultural Heritage Management and Sustainable Development* (2011).

In addition, several more general archaeology journals regularly include content on heritage issues. Aside from the revived "Antiquities Trade" feature in *JFA*, the *Journal of Social Archaeology* (2001) and the journal of the World Archaeological Congress, *Archaeologies* (2006), both seek to examine the social and political context of archaeological practice and thus often include articles on conflicts and policies dealing with heritage worldwide.

World Heritage List: Criteria, Inscription, and Representation

Michael A. Di Giovine
Department of Anthropology and Sociology, West Chester University of Pennsylvania, West Chester, PA, USA

Introduction

It has been said that World Heritage is a category and the World Heritage List is its instrument

(Hafstein 2009: 108). While categories themselves are mechanisms for organizing information and making meaning of them (cf. Evans-Prichard 1976: 222–225; Lévi-Strauss 1966), a list "brings greater visibility" to them, rendering them bounded and defined yet at the same time abstracted (Goody 1977: 81). The category of "world heritage" is not universally comprehended but rather must be effectively constructed, communicated, and standardized in meaning to meet the world's varied understandings of culture, heritage, and patrimony and to convey UNESCO's principle objectives. The World Heritage List accomplishes this; it converts places primarily of local import into sites publically recognized as possessing universal value through a complex, ritual process that engages actors from local, regional, national, and transnational realms. This entry will outline the major turns of thought in the development of the List, process of inscription, criteria used to define the sites, and key issues and current debates surrounding the List's representative quality.

Definition

The World Heritage List is the primary instrument that constructs the universalized category of "World Heritage" by cataloguing the diverse worldwide sites that are determined to possess "outstanding universal value." Because the individual sites are so disparate and the criteria for their inscription so conceptual, the List's construction of world heritage exists through its inherent juxtapositionality. That is, the List allows each site to be seen in juxtaposition to all of the other World Heritage sites, and therefore, what constitutes world heritage is complexified, conceptually deepened, and expanded as more sites are inscribed on the List over time (Di Giovine 2010). It is a "mechanism of display" akin to a public speech (Hafstein 2009: 97) or a map, which lends conceptual coherence to what Di Giovine (2009) calls UNESCO's heritage-scape, an alternative geographical rendering of the world in which World Heritage sites, rather than political capitals, are the focus. Critics have argued that, over time, the List has changed from a measure aimed at preservation to a branding mechanism for touristic consumption (Ryan and Silvanto 2009).

Although the List strives to be inclusive enough to construct the World Heritage Convention's metanarrative of "unity in diversity," like all lists, it innately indexes a particular structural order and value-based hierarchy (Schuster 2002), which often creates a high level of competition at numerous levels. On the one hand, since the List is organized primarily by state-party, it is often implicitly believed that the more sites a state possesses, the higher the value and legitimacy of that nation. On the other hand, the List maintains a level of exclusivity and competition within a nation-state by including only sites that are deemed to meet its criteria of "universal value." UNESCO itself has asserted that not all sites "of local or natural interest, which are quite justifiably a source of natural pride," possess universal value (cf. UNESCO 2005b: 4). Competition therefore may occur when one community, group, or nation succeeds in designating its site while another fails in its effort to designate a similar property.

Key Issues

The World Heritage Criteria

The World Heritage Criteria consists of a set of ten typologies, or idealized categories, which are used to evaluate, and offer the conditions for, a site's inscription on the World Heritage List. They are concerned with identifying a site's "outstanding universal value," which, in turn, would guide state-parties in constructing management and conservation plans for their World Heritage properties (UNESCO 2005b: 12). The *Revised Operational Guidelines* defines "outstanding universal value" as:

> cultural and/or natural significance, which is so exceptional as to transcend national boundaries and to be of common importance for present and future generations of all humanity. As such, the permanent protection of this heritage is of the highest importance to the international community as a whole. The Committee defines the criteria for the inscription of properties on the World Heritage List. (2005a: 24)

The typologies were established in the World Heritage Convention (UNESCO 1972) and identified in the first *Operational Guidelines*, passed in 1978. At this time, cultural and natural sites were evaluated separately, based on "two sets of criteria" (1978: 1), but 25 years later, the two criteria were merged into one set of ten typologies, with the first six being the "cultural" criteria and the last four being the formal "natural" criteria (see UNESCO 2003b). This went into effect in the 2005 *Revised Operational Guidelines*, which stated that a property is recognized as possessing "outstanding universal value" if one or more of the following criteria are met:

1. Represent a masterpiece of human creative genius.
2. Exhibit an important interchange of human values, over a span of time or within a cultural area of the world, on developments in architecture or technology, monumental arts, town planning, or landscape design.
3. Bear a unique or at least exceptional testimony to a cultural tradition or to a civilization which is living or which has disappeared.
4. An outstanding example of a type of building, architectural or technological ensemble, or landscape which illustrates (a) significant stage(s) in human history.
5. Be an outstanding example of a traditional human settlement, land use, or sea use which is representative of a culture (or cultures) or human interaction with the environment, especially when it has become vulnerable under the impact of irreversible change.
6. Be directly or tangibly associated with events or living traditions, with ideas, or with beliefs, with artistic and literary works of outstanding universal significance (The Committee considers that this criterion should preferably be used in conjunction with other criteria).
7. Contain superlative natural phenomena or areas of exceptional natural beauty and aesthetic importance.
8. Be outstanding examples representing major stages of earth's history, including the record of life, significant ongoing geological processes in the development of landforms, or significant geomorphic or physiographic features.
9. Be outstanding examples representing significant ongoing ecological and biological processes in the evolution and development of terrestrial, fresh water, coastal, and marine ecosystems and communities of plants and animals.
10. Contain the most important and significant natural habitats for in situ conservation of biological diversity, including those containing threatened species of outstanding universal value from the point of view of science or conservation.

The criteria's wording is extremely important for assimilating disparate sites into a cohesive List and for crafting the universalizing narrative individual sites possess. Instead of indicating concrete categories, the typologies are purposefully vague, so as to be applicable to a wide variety of places across the globe. Rather than *being* something definite, these sites are intended to *represent*, *exhibit*, *bear testimony to*, *exemplify*, or be *tangibly associated with* generalized forms, cultural traditions, ideas, and human abilities that are loosely defined and easily interpreted in multiple ways. They are, in a way, empty signs whose values and meanings can be filled in by different parties throughout time. It is a testament to the universal applicability of the criteria that, while the *Operational Guidelines* have progressively modified the conceptions of what constitutes "outstanding universal heritage," the actual typologies have remained the same as they were outlined in the Convention.

Authenticity and Integrity

Furthermore, the World Heritage Convention stipulates that a site must also meet a standard of "authenticity" (for cultural sites) or "integrity" (for natural sites). Like the typologies, these were originally separate categories but were merged in the 2005 *Revised Operational Guidelines*.

Stemming from the Venice Charter (ICOMOS 1964) and reconceptualized most significantly in

the Nara Document on Authenticity (UNESCO 1994b), UNESCO's understanding of authenticity rests on the notion that a property's outstanding universal value is "truthfully and credibly expressed" through the form, design, materials, and functionality. This includes "subsequent modifications or additions" (1978: 4). Following the "Cairns Decision" (UNESCO 2000), intangible heritage, spirit, and sense of place were also added in an attempt to better accommodate non-Western value systems (2005a: 21).

The *Revised Operational Guidelines* expanded "integrity" to encompass all sites under consideration, and state-parties are now required to submit a statement of integrity for each property nominated. By integrity, UNESCO means "the measure of the wholeness and intactness of the natural and/or cultural heritage and its attributes" (2005a: 22). The typologies for integrity are both conceptual and concrete: On the one hand, a site must include "all elements necessary to express its outstanding universal value"; on the other hand, the designated site itself must be of an adequate size to appropriately represent such values. Furthermore, the statement must include a thorough assessment of the site's state of conservation as well as ongoing development projects that may threaten the integrity of the proposed World Heritage site (such as its geographic boundaries and buffer zones, its cultural or natural resources, or its aesthetic qualities and vistas). Threats to a site's integrity are most often invoked when protesting subsequent government interventions in and around a World Heritage site.

The Process of Inscription

The process of inscription has changed little since it was originally outlined in the 1972 World Heritage Convention, despite substantial changes in UNESCO's conceptualization of what constitutes "heritage."

Because UNESCO is an intergovernmental body, the inscription process begins with a participating state-party, which must offer up its cultural property for inscription; the few exceptions to this rule include Cambodia's Angkor Archaeological Park and Afghanistan's Bamiyan Buddhas, which were both designated while the countries were under United Nations-led transitional governments. To nominate a site, the state-party must be a signatory to the World Heritage Convention, paid its annual dues to the World Heritage Fund, and included the site on its Tentative List. Each signatory has its own Tentative List, an inventory or wish list of properties it intends to nominate. It can be as extensive or as brief as the nation deems appropriate and can be indefinitely modified as the state-party adds or withdraws a property from the nomination process.

Once a property is added to the state-party's Tentative List, a Nomination File is opened at the World Heritage Centre in Paris, which will contain all of the appropriate documentation concerning the site: maps, figures, images, precise coordinates of the area to be considered (including proposed buffer zones), relevant historical records, letters of endorsement by important figures, previous academic studies on the site, current and future management and preservation plans, as well as an official description of the site attesting to its universal value, authenticity, and integrity that is based on the World Heritage Criteria.

These data will then be analyzed by UNESCO-approved Advisory Bodies, nongovernmental organizations specializing in historic preservation or nature conservation. Cultural sites are assessed by the International Council of Monuments and Sites (ICOMOS) and natural sites by the International Union for Conservation of Nature (IUCN); both also conduct on-site research to evaluate the proposed monument and its management. A third Advisory Body, the International Centre for the Study of the Preservation and Restoration of Cultural Property (ICCROM), will be contacted should the site require an assessment of past or proposed restoration work. In their written report, the Advisory Bodies assess how the proposed property meets or falls short of the criteria outlined in the World Heritage Convention. This is less an act of evaluation as it is of idealization, for it effectively changes the property into an idealized material form of UNESCO's metanarrative of "unity in diversity" (Di Giovine 2009: 199).

Once the File is complete, it can be presented at the annual meeting of the World Heritage Committee, which is composed of 21 representatives of state-parties who are elected from the General Assembly. The Committee examines each nomination based on the technical evaluations and votes to inscribe or reject a site. They may also vote to defer judgment on a site, requesting additional information from the state-party. Along with a site's inscription, the Committee confirms the textual wording of the site's designation; often it is a slight modification of the Advisory Body's statement of the site's "outstanding universal value." However, the importance of this act should not be underestimated; it is often subject to politicking as other parties struggle to determine the site's specific narrative, which will translate to the ways in which the site is conserved and packaged for touristic consumption (Di Giovine 2009, 2010). Finally, the World Heritage Committee inscribes the new World Heritage site's name and geographic location on the List, along with other similarly valorized places.

The List of World Heritage in Danger

At its annual meeting, the World Heritage Committee also reviews the state of conservation and management of World Heritage sites. If they find threats to a site's integrity or other characteristics that determined its inscription on the World Heritage List, the Committee may vote to inscribe the property onto the List of World Heritage in Danger, a separate List designed to alert the international community to elements threatening a World Heritage site. These can be "ascertained" dangers – "specific and proven" threats such as warfare, pollution, destruction, or other risks to the site's integrity – or "potential" dangers that may threaten the characteristics for which the site was designated (UNESCO 2005a: 47–49). The List is perceived differently by state-parties; some see it as an instrument to raise awareness of their site and to generate international support (monetary and technical) to help protect it; others see it as a dishonorable sanction. Nevertheless, upon inscription on the List of World Heritage in Danger, a state-party must take corrective action.

Delisting

The *Operational Guidelines* also provides the possibility that a site can be delisted if a state-party does not comply with the corrective measures required when the property was inscribed on the List of World Heritage in Danger. Informed by Article 4 of the Convention – "Each state party to this Convention recognizes that the duty of ensuring the identification, protection, conservation, presentation and transmission to future generations of the cultural and natural heritage referred to in Articles 1 and 2 and situated on its territory, belongs primarily to that State" – this rare action has, to date, been exercised when the state has failed to adequately protect a site's integrity. For example, Oman's Oryx Sanctuary was delisted in 2007 after the nation-state reduced the boundaries of the natural park by 90%, began fossil fuel extraction within the sanctuary, and did not enforce animal poaching laws, which resulted in nearly eradicating the Oryx population (when the site was delisted, only four breeding pairs remained). While national policies affected Oman's World Heritage site, Germany's Dresden Elbe Valley was delisted in 2009 after the federal government was legally unable to halt the Saxony region's construction of a bridge over the Danube, which UNESCO deemed would threaten the integrity of the panorama for which the site had been inscribed. While it is incumbent for a state-party to be a member in good standing before designating a site, UNESCO has indicated that a site cannot be delisted if the state-party's status changes, as occurred in 2011 when Thailand announced its withdrawal from the World Heritage Convention over Cambodia's contested designation of Preah Vihear.

Representation and the Transformation of the World Heritage List

The World Heritage List is very much a process and must be seen in its ongoing sociohistorical context (cf. Francioni 2008: 5). Since its inception in 1972, the List has changed from including predominantly Western religious monuments to living cultural landscapes, transboundary itineraries, and contemporary constructions. Indeed, these marked changes best illustrate the criteria's

effectiveness to adapt to changing conceptions of heritage while maintaining the same wording of the typologies.

The Nature/Culture Dichotomy and the Creation of "Cultural Landscapes"

Article I of the 1972 World Heritage Convention lists three general forms of cultural heritage that were to be considered for listing:

- *Monuments*: architectural works, works of monumental sculpture and painting, elements or structures of an archaeological nature, inscriptions, cave dwellings, and combinations of features, which are of outstanding universal value from the point of view of history, art, or science
- *Groups of buildings*: groups of separate or connected buildings which, because of their architecture, their homogeneity, or their place in the landscape, are of outstanding universal value from the point of view of history, art, or science
- *Sites*: works of man or the combined works of nature and man, and areas including archaeological sites, which are of outstanding universal value from the historical, aesthetic, ethnological, or anthropological point of view

These are built structures ("architectural" and "archaeological" are the main terms used) and are valued predominantly for their aesthetic qualities, scientific import, and historical longevity. Indeed, they are all considered monumental, in that they are specifically meant to be devices to trigger one's memory and can be keys to scientifically understanding past peoples and their cultures. Preservation of their authentic, material forms is therefore a primary concern. As UNESCO wrote in a treatise that predated the Convention, "Historic monuments are the adornments with which Man has decked the earth; they are the common heritage of mankind and remind us that civilization is made up of contributions from all peoples, and that technique has ever gone hand in hand with the cult of the beautiful, and the taste for the new with the search for the imperishable" (1970: 9). Such conceptualization of material culture as monumental, valued for its imagined existence in the past, has been subject to critiques that argue that the List artifactualizes or museumifies otherwise living cultural properties (cf. Lowenthal 1998).

Just as Article I of the World Heritage Convention identified "cultural" sites in terms of their aesthetic or scientific value, so too did Article II define "natural" sites:

- *Natural features* consisting of physical and biological formations or groups of such formations, which are of outstanding universal value from the aesthetic or scientific point of view
- *Geological and physiographical formations* and precisely delineated areas which constitute the habitat of threatened species of animals and plants of outstanding universal value from the point of view of science or conservation
- *Natural sites* or precisely delineated natural areas of outstanding universal value from the point of view of science, conservation, or natural beauty

Natural sites, then, were conceptualized as "exceptional natural sites and national parks without people" (Rössler 2006: 334). Just as it is incumbent to preserve cultural monuments from the natural transience of time, so too is it imperative to conserve natural sites from human intervention (Fowler 2003: 15). Such oppositional definitions, therefore, not only created a problematic distinction but also antagonism between the two categories. Indeed, although the Convention allows for sites to be designated as "mixed" – an almost one-to-one "combination" of natural and cultural elements – there are comparatively very few, and experts have found it not only ineffective but "intellectually flaccid" (Fowler 2003: 18).

This Enlightenment-era division between nature and culture has been critiqued by social scientists, who point out that these two categories are rarely, if ever, mutually exclusive. Humans are a part of nature (cf. Papayannis and Howard 2007), and places, by their very demarcations (which are necessary for the nomination File), are cultural (Pearson and Richards 1997: 5). Furthermore, since these "parks without people"

often did have human communities living within their boundaries, a "natural" designation seems to implicitly consider them as *naturvölk*, primitives lagging behind the world's civilizational trajectory (cf. Morgan 1877; Herder [1891]1966). Particularly when such indigenous communities espouse different views of material culture and monumentality, this frequently causes an undervaluation of indigenes' culture, leading to their marginalization; under the guise of conservation, these minorities are considered a nuisance to be educated, modernized, or removed (cf. Smith 2006; Di Giovine 2009: 234–259).

In response to social scientists' critiques of this dichotomy, a third category of "cultural landscapes" was added to the *Operational Guidelines* in 1992 after many years of debate within UNESCO. Coined by human geographer Carl Sauer (1925) and subsequently retheorized a number of times since (see Wagner and Mikesell 1962; Birks et al. 1988), the term focuses on the interactions between humankind and the natural environment. Its justification rests on Article 1 of the Convention text, which points out that World Heritage broadly consists of the "combined works of nature and man" (UNESCO 1994c: 13–14). As with natural and cultural sites, UNESCO specifies three forms of cultural landscapes:

1. *Clearly defined landscapes* designed and created intentionally by humans, such as many gardens and parks. Such landscapes had been already included on the World Heritage List in the early years such as Versailles in France, but the concept opened the List for sites such as Kew Gardens in the United Kingdom or the large-scale extended designed area of the Lednice-Valtice Cultural Landscape in the Czech Republic.
2. *Organically evolved landscapes*, which can be either relict landscapes or continuing landscapes. This results from an initial social, economic, administrative, and/or religious imperative and has developed its present form by association with and in response to its natural environment. Such landscapes reflect that process of evolution in their form and component features. These include a number of agricultural landscapes ranging from the tobacco landscape of Vinales Valley in Cuba, the Rice Terraces of the Philippine Cordilleras, or the Puszta pastoral landscape of Hortobagy National Park in Hungary.
3. *Associative cultural landscapes*. The inclusion of such landscapes on the World Heritage List is justifiable by virtue of the powerful religious, artistic, or cultural associations of the natural element rather than material cultural evidence, which may be insignificant or even absent. This type is exemplified by Uluru-Kata Tjuta in Australia, Sukur in Nigeria, and Tongariro National Park in New Zealand (Rössler 2006: 335–336).

Rather than eliminating the nature-culture divisions, the category therefore was meant as a bridge between the two, to provide a category where human interaction upon the natural environment was clearly evident. In particular, "associative cultural landscapes" were meant to accommodate alternative forms of heritage by minority groups whose cultural production is primarily immaterial; examples of such sites are Uluru in Australia, Sukur in Nigeria, and Tongariro in New Zealand. In addition to nominating properties as "cultural landscapes" outright, "mixed" sites can be recategorized as cultural landscapes, as Uluru, Sukur, and Tongariro were. Cultural landscapes are marked as "cultural sites" on the World Heritage List and its associated map (http://whc.unesco.org/en/list).

Thana Sites and "Negative World Heritage Sites"

While the List is intended to reveal the unity of humanity in the diversity of its creations (Di Giovine 2009, 2011), a few sites have been inscribed which are neither valued for their aesthetics nor reveal their physical endurance throughout time. These are places of warfare, genocide, and destruction, "dark" or thana sites that are of interest to the newly increasing trend of "dark tourism" or "thanatourism" (see Seaton 2009; Sharpley and Stone 2009). Rather than revealing "unity in diversity" as traditional

World Heritage sites do, they can be considered "negative World Heritage sites" (Di Giovine 2009: 124–132; cf. Meskell 2002) for they were designated as exemplars of the destructive nature of war and cultural intolerance, as were the Nazi concentration camp of Auschwitz (designated in 1979, the 2nd year of World Heritage inscriptions), Hiroshima's "A-Bomb" Dome, or the empty spaces in Afghanistan's Bamiyan Valley where the immense Silk Road-era Buddhas stood before they were destroyed by the Taliban in 2001. Although each of these examples viscerally reveals the more destructive side of humanity, UNESCO puts a unifying spin on the narrative by downplaying specific geopolitics in favor of generalities concerning humankind and the need to create world peace, issuing a warning of future strife should diversity be universally undervalued.

Disproportionate Representation and the 1994 Global Strategy

From the mid-1980s onward, it was generally perceived inside and outside of UNESCO that its definition of "cultural heritage" as solely aesthetic and monumental was outdated (Pressouyre 1993; UNESCO 1994a: 2–3). In response, UNESCO commissioned a sweeping study of the List. The study found certain "overrepresentations" of Western categories of what was considered of universal value, including monuments, historic towns, religious buildings, and "elitist" architecture; these sites came mostly from "historical periods" rather than from prehistoric ages or the twentieth century. It also found that Christianity and Europe were overrepresented compared to other religions and other parts of the world. The ensuing *Global Strategy for a Balanced*, *Representative and Credible World Heritage List* (1994a) addressed these issues by broadening the definitions of cultural and natural heritage, paying particular attention to alternative forms of cultural heritage found in underrepresented parts of the world. A primary goal of the *Global Strategy* was to encourage nation-states in underrepresented regions – such as Africa and the Pacific Islands – to join the Convention by providing incentives and sending Advisory Bodies to work closely with these countries to nominate their properties. In the "Cairns Decision" (UNESCO 2000), the World Heritage Committee definitively established a quota system whereby each nation could only nominate one new property per year; this was an attempt to lessen the ever-increasing gap between underrepresented nations and Western European countries such as Italy who would consistently inscribe several sites per year. The "Budapest Declaration" of 2002 reaffirmed UNESCO's commitment to encourage developing nations to join the Convention by pledging to help ensure sustainable development and more community involvement.

The Cairns Decision also allowed an important exception to this rule: In addition to requesting an unlimited amount of extensions (increasing the geographic size of a preexistent World Heritage site), countries could nominate an unlimited amount of transboundary or multisited World Heritage properties. While originally conceived as sites that straddle the borders of multiple countries (i.e., large natural parks in Africa or the Americas), they also include networks of individual properties that are thematically linked, such as the archaeological remains of the "Frontiers of the Roman Empire," the Jesuit missions of Guaranis in Argentina and Brazil, or the colonial Mountain Railways of India. The network paradigm is becoming increasingly popular within nation-states themselves; the "Longobards in Italy, Places of Power" network consists of seven locations across Italy in which the Lombard invaders established power centers. "Itineraries" that trace pilgrimage or trade routes have also become popular, although the medieval European pilgrimage route to Santiago de Compostela is listed separately under France and Spain instead of as one transboundary site. To inscribe more "contemporary" properties, the Global Strategy has also reconceptualized the importance of aesthetics. While "industrial heritage sites," such as the UK's perfectly planned workmen's city of Saltaire or Delhi's Victoria Station, have a classic aesthetic quality to them, others such as the abandoned salt and coalmines northeastern Europe do not. And although "underwater cultural heritage" is regulated by a different, less-binding Convention (UNESCO 2001), it is conceivable that the

World Heritage List may include these sunken remains of human interaction (such as shipwrecks or the submerged city of Alexandria, Egypt) in the future.

If the goal of the Global Strategy was to engage more nation-states and to distribute World Heritage designations more evenly throughout the world, it has proven to be fairly effective. When the Strategy was enacted in 1994, only 135 nations had ratified the Convention; in the span of a decade, nearly all became signatories. While Western Europe still counts the highest density of World Heritage sites, the List is indeed becoming more evenly distributed. Most importantly, the Global Strategy has helped complexify the very notion of heritage, allowing more flexibility and greater anthropological understanding of the ways in which "heritage" is conceived of, manifested, and valued (see Di Giovine 2015).

Future Directions

The Representative List of Intangible Cultural Heritage

While explicitly attempting to address alternative notions of heritage, the creation of "associative cultural landscapes" and the *Global Strategy* did little to alleviate tensions among developing nations and aboriginal groups whose cultures were predicated more on immaterial practices than the creation of monumental material cultural forms. UNESCO responded by taking progressive steps toward defining, valorizing, and safeguarding intangible cultural heritage. Building on a failed 1989 *Recommendation for the Safeguarding of Folklore and Traditional Culture*, a Korean proposal to create a "World Living Human Treasures List, similar to the World Heritage List" (UNESCO 1993: 2), and a sweeping study of intangible heritage (UNESCO 1996), in 1997 UNESCO adopted a resolution creating the *Proclamation of Masterpieces of the Oral and Intangible Heritage of Humanity*, a type of List that was not, however, subject to a Convention and had no financial resources at its disposal (Hafstein 2009: 95). Though it was intended to "proclaim" the top forms of immaterial heritage, it went largely unnoticed in comparison to the World Heritage List; it was also criticized by many of the same indigenous groups as being too hierarchical and elitist and without adequate reliance on the participation of the communities producing such masterpieces. While all groups pushed for a Convention that would provide legal instruments similar to that of the World Heritage Convention, they were divided in their desire for a List; one faction felt that a selective List would be the only adequate way of raising the necessary awareness for safeguarding these practices, while the smaller nations wished to eschew lists altogether (or at least a selection process), which they perceived as unconditionally elitist. The final product, *The Representative List of the Intangible Cultural Heritage of Humanity*, and its associated *List of Intangible Heritage in Danger* (2003a), represents a compromise between the two: While still selective in its process of inscription, it eschews "universal value" as its primary criterion in favor of "representivity" (Hafstein 2009: 108); each signatory draws up a complete inventory of its cultural practices and is encouraged to submit one for inscription during the Intangible Heritage Committee's biennial meeting. It thus builds on the basic structure of the World Heritage List yet purports to be more democratizing and even less determinate in its standards of selection – thus attempting to preclude a situation of unbalanced representationality that the Global Strategy was forced to correct.

The Representative List of Oral and Intangible Cultural Heritage seems to be a key development for the evolution and survival of the World Heritage List. While separate, both lists are inexorably linked historically, conceptually, and, to a certain extent, even procedurally. One was born from the other so that the other could remain relevant amid changing conceptions of heritage. Indeed, the World Heritage List has progressively moved from including sites primarily conceived of as artifactual and monumental to those that espouse more holistic, living notions of heritage. Importantly, intangible heritage designations have quickly been met with similar celebrations at the local level in many societies across the world, and in its early years, locals often conflated the Intangible Heritage List with that of the World Heritage List.

Particularly following the Yamato Declaration, in which participants agreed to create a more integrated approach toward safeguarding both tangible and intangible heritage (UNESCO 2004), it is conceivable that the Intangible Heritage list, while remaining separate and decidedly less place-oriented, will implicitly inform future nominations by state-parties, as well as future actions by the World Heritage Convention.

World Heritage Objectives and Outcomes

Introduction

UNESCO's (1972) World Heritage Convention describes its purpose primarily in terms of preserving "natural" sites and built "cultural" structures, such as unique landforms, monuments, and archaeological remains. Yet by the 40th anniversary of the Convention's ratification, Irina Bokova, UNESCO's then-director general, reacted to the destruction of World Heritage-listed properties in Timbuktu, Mali, in these words: "Let's be clear. We are not just talking about stones and building. This is about values, identities and belonging. . . . [W]e must start seeing cultural heritage as an international security issue" (Bokova 2012). While her statement may at first signal a shift in the World Heritage Convention's goals – from preservation to peacemaking – a closer analysis of UNESCO's major documents, pronouncements, and practices reveals multiple, complex, and intersecting objectives, which are met with varying degrees of success and produce often unexpected outcomes. This entry will examine the World Heritage Convention's objectives in the short term, medium term, and long term, arguing that they nested and are interdependent; it will also show how these interrelated goals ultimately factor into UNESCO's broader, global peacemaking objectives.

Definition

Founded in 1945 as a specialized arm of the United Nations, UNESCO was born in the wake of the tragedies of World War II. UNESCO's role as the United Nations Educational, Scientific and Cultural Organization

was to delve beyond traditional diplomacy and economically oriented programs and engage directly with publics at more intangible levels for the ultimate goal of building "peace in the minds of men" (UNESCO 2003b: 1). This tactic of public diplomacy is predicated on the idea, espoused in the Preamble to UNESCO's Constitution, that "the wide diffusion of culture, and the education of humanity for justice and liberty and peace are indispensable to the dignity of man and constitute a sacred duty which all the nations must fulfil in a spirit of mutual assistance and concern" and that "a peace based exclusively upon the political and economic arrangements of governments" is insufficient and "must therefore be founded, if it is not to fail, upon the intellectual and moral solidarity of mankind" (UNESCO 1945: 1). While this statement does not mention heritage sites per se, it provides the foundation for the World Heritage Convention's emphasis on the collective responsibility toward promoting "the wide diffusion of culture" and education concerning "each other's ways and lives" (1945: 1) – for which World Heritage sites would become metonyms.

Historical Background

Abu Simbel: A Precursor to the World Heritage Convention

In the mid-1950s, Egyptian president Gamal Nasser announced plans to construct the Aswan High Dam at the first cataract of the Nile to regularize the river's flooding, improve the region's agricultural landscape, and symbolically modernize the country in the eyes of the world. The plan called for the construction of a reservoir which would completely submerge a temple complex constructed by Pharaoh Ramses II (1303–1213 BCE). At the behest of Egypt and the Sudan, in 1960 UNESCO launched an unprecedented international campaign to move the temples to higher ground through a technologically ambitious plan (see *Time Magazine* 1963; UNESCO 1980). Over 40 member states raised $80 million – nearly double the planned cost – and sent teams of archaeologists to excavate the "practically virgin land" together (UNESCO 1982: 30), while international engineers succeeded in saving the temples. Abu Simbel had a profound effect on the future of World Heritage, and UNESCO proclaimed it "a triumph of international solidarity" (UNESCO 1982). It revealed the strong emotional relationship that such heritage properties – and the prospect of their transience – could exert on the international community, irrespective of national origins, and brought nations and experts together for the common goal of researching, and preserving, these monuments.

The World Heritage Trust and Creation of the World Heritage Convention

It was in the glow of the Abu Simbel success that, in 1965, a White House conference called for the creation of a "World Heritage Trust" to engage the international community in the preservation of exemplary sites "for the present and future of the entire world citizenry" (quoted in UNESCO 2008b: 7). A plan of conservation was adopted which was similar to that of the US National Parks service. The idea of a World Heritage Trust undoubtedly gained international traction when, the following year, UNESCO launched the immensely successful "Save Venice" campaign in response to the devastating floods that rocked the northern part of Italy. In 1968, the International Union for the Conservation of Nature (IUCN) followed suit in adopting a similar framework for its membership. These proposals were combined in 1972, when delegates to the United Nations Conference on the Human Environment in Stockholm called for a new Convention that could better ensure the safeguarding and management of cultural and natural properties. Later that year, it became the World Heritage Convention (*Convention Concerning the Protection of the World Cultural and Natural Heritage*) spearheaded by UNESCO, which created a World Heritage Committee that oversees the general body of state-party delegates to the Convention, and a small World Heritage Fund comprised of mandatory donations by each member state. Implicit in the Convention text, and in subsequent publications sponsored by UNESCO and the World Heritage Centre, are a number of

interlinked short-term, medium-term, and long-term objectives.

Key Issues

Short-Term Objectives: Knowledge Creation and Dissemination

While the World Heritage Convention is explicitly concerned with preserving tangible natural and cultural heritage, interestingly, the Convention grants the World Heritage Committee only limited power to affect such ambitious goals as cultural preservation, sustainable development, and peacemaking. Rather, the Committee is only invested with the short-term ability to create and diffuse alternative narratives concerning the universal value of heritage sites by evaluating and inscribing a property onto the World Heritage and World Heritage in Danger lists and by disseminating these lists through diverse channels and global networks. These are fundamentally acts of knowledge creation and dissemination. Furthermore, moneys can be disbursed from the relatively small World Heritage Fund primarily for use in needs assessments and Advisory Body evaluations (necessary for the nomination of a site), publicity campaigns by state ministries to raise awareness of a site's World Heritage designation, and capacity-building and technical assistance programs, such as exchanges between site managers in developing countries with those in Europe (Di Giovine 2009a: 315–319; UNESCO 1972: 12–13). While it is believed that these awareness-raising campaigns will inspire international conservation and tourism efforts in the medium term, they are also directed toward locals, "to strengthen appreciation and respect. . .of the cultural and natural heritage as defined in Article 1 and 2 of the Convention" (1972: 13).

Although UNESCO has some control over the knowledge they produce and diffuse, they have little control over the way it is interpreted, used, and reproduced by state parties and other actors. In particular, while each site is meant to reveal UNESCO's claim of "unity in diversity," actors may emphasize a particular aspect of the place's history to valorize certain groups and marginalize others, as frequently occurs to minority or indigenous populations living on or near the designated site and who may attribute alternative use values to it. Designations, however, are intended to increase the "prestige factor" of a site (cf. Dure 1974) – important for the generation of preservation and tourism campaigns – but often lead to emotionally charged competition between nation-states who quantify their value based on the number of sites they have on the list. In some cases, this may even exacerbate geopolitical tensions, leading to civil strife – such as periodic riots between Cambodians and Thais over Angkor Wat or the political and military actions taken by these same countries upon the designation of Preah Vihear as a Cambodian World Heritage site in 2008.

Medium-Term Objectives: Preservation and Tourism Development

Safeguarding Cultural and National Properties

Although it is not invested in the direct ability to conduct historic preservation and natural conservation projects, UNESCO's *Convention for the Protection of the Cultural and Natural Heritage* is first and foremost aimed at safeguarding cultural and natural resources deemed to be of "universal value," the "heritage of mankind" (1972: 1). UNESCO attempts to fulfill this objective first through *normative actions* and second through *coercive actions*.

Normative actions involve the institution of norms, procedures, and requirements a state party must satisfy before nominating their site for World Heritage status. These include thorough research concerning the proposed site's history, topography, universally valorized qualities, authenticity, and integrity, the intervention of expert "Advisory Bodies" who assess the site's integrity and level of authenticity on behalf of UNESCO, and the drafting of conservation and management plans. State parties in good standing to the World Heritage Convention may receive some funding for these endeavors, although the Operational Guidelines specify that the fund should ultimately "be used to mobilize additional funds for International Assistance

from other sources" (UNESCO 2008a: 60). Such actions contribute to UNESCO's goal of knowledge creation while, at the same time, also induce the nation-state to ensure the site's preservation by cooperating with the international community (cf. UNESCO 1972: 3). Furthermore, once a site is inscribed on the World Heritage List, state parties are required to submit periodic assessments both on the site ("reactive monitoring") and on the implementation of the World Heritage Convention in its territory ("periodic reporting") and to make any modifications to the management of its site (2008a: 45–47, 54–56).

Should these norms not be fulfilled, UNESCO may take *coercive action* by inscribing the property on the List of World Heritage in Danger and calling for specific, time-sensitive responses on the part of the state party in question. Noncompliance may result in the site's delisting (UNESCO 2008a: 28, 52–53). However, coercive actions should not simply be understood as a means of compelling nation-states and groups to act through negative reinforcement and threats of sanction, but also through the prospect of raising a group's symbolic capital in the international community. In its *World Heritage Information Kit*, UNESCO makes clear its belief that such claims to prestige directly foster conservation projects (2008b: 9).

While inscription on the World Heritage List in Danger is sometimes perceived by a state as a penalty, it also is intended to serve as an extra awareness-raising mechanism directed toward international communities, one that creates a sense of urgency for sites that are in particular danger, as the cases of Abu Simbel and Venice successfully revealed. Further underscoring the believed link between knowledge dissemination and preservation, in 2002 the World Heritage Committee adopted *the Budapest Declaration on World Heritage*, which invited "all partners to support World Heritage conservation through key strategic objectives known as the 'Four Cs': strengthen Credibility of the World Heritage List; ensure effective Conservation of World Heritage properties; promote the development of effective Capacity-building measures; increase public awareness and support through Communication" (2008b: 8, see 2002a).

Although grounded in egalitarianism, UNESCO's emphasis on preservation, as well as its tactics, has drawn criticism. On the one hand, while a World Heritage site is "supposed to be protected by the world community, under normal circumstances it is directly managed by the nation in whose political boundaries it is located" and who may not share in UNESCO's ideological interests (Di Giovine 2009a: 7); a site's conservation is ultimately carried out at the country's discretion and is subject to national law (UNESCO 1972: 3–4). Should UNESCO's coercive power fail, it has little recourse but to delist a site, which does nothing to directly protect it from further destruction. On the other hand, scholars have pointed out that conservation often denies a monument's total life history, taking the site back to an idealized and historicized state that "tempts us to ignore our own influence on them" (Lowenthal 1998: 114), conserving only one of many possible narratives embodied in the structure through time and destroying or erasing others (Di Giovine 2009a: 359). In the name of conservation, site managers often prevent alternative uses by indigenous populations while at the same time paradoxically prohibiting those same populations to "modernize" their technologies or living practices in the name of preserving authenticity (see Di Giovine 2009b; Smith 2006). There also runs the risk of privileging the needs of international tourists, rather than those of local communities. Indeed, it was only in 2007 that the World Heritage Committee officially recognized "the fact that conservation, capacity building, credibility and communication are all intrinsically linked to the role of community" (UNESCO 2008b: 8, cf. 2007).

Heritage Tourism and Development: An Uneasy Alliance

UNESCO has historically expressed ambivalence toward tourism development, even while conducting limited normative actions (requiring management plans to account for tourism impacts), and promoting *inspired actions* among tourists by supporting publicity campaigns by

governmental ministries and industries involved in tourism. "Tourism" is not mentioned in the World Heritage Convention, and the phrase "tourist development projects" appears only among a list of possible threats to World Heritage sites that could provide the basis for inscription on the World Heritage List in Danger (see UNESCO 1972: 6). Interestingly, though, a majority of the early World Heritage sites were already well known to, if not also well visited by, international audiences.

UNESCO's ambivalence toward tourism seems to stem from the early failures by the UN and other intergovernmental organizations in tourism development. The World Heritage Convention was ratified when expectations of tourism as a means of peaceful economic development were at their height. The United Nations granted the nascent International Union of Tourism Officers (IUOTO) consultative status in 1954; the UN held its first conference on international tourism in Rome in 1963, where it outlined a framework for tourism development, it declared 1967 International Tourism Year (ITY) with the slogan "Tourism: Passport to Peace," and it finally absorbed IUOTO into the newly created United Nations' World Tourism Organization in 1970 (UNWTO 1974, 1975; Jafari 1975). More concretely, in 1969 the World Bank had created a dedicated Tourism Projects Department which lent over $525 million between 1970 and 1979 to "support tourism as an economic growth tool" for 18 countries that met specific criteria (Hawkins and Mann 2007:354; Di Giovine 2009a: 216). It is important to note that UNESCO stayed on the sidelines. Indeed, a study commissioned by UNESCO – which was published as the monograph, *Tourism: Passport to Development?* (de Kadt 1979) – found that the predicted "multiplier effect" of direct and indirect employment that could revitalize developing countries did not materialize (UNESCO 1976: 81); rather, the industry's proclivity to vertical and horizontal integration created foreign monopolies that largely relegated locals to the sidelines and allowed for notable "leakages" – the proportion of monies invested or earned in the tourism sector that ended up overseas (Markandya et al. 2005: 231), mostly in the hands of the tourists' countries of origin (Bryden 1973). Furthermore, it did not stave off a "flight from the land" by farmers who continued to move to cosmopolitan urban centers in search of work (UNESCO 1976: 81). In 1979, the World Bank followed suit, issuing its own study, which acknowledged drawbacks to tourism development in the absence of adequate planning on the part of the developing nation (Norohona 1979), and by the mid-1980s, it ceased taking on tourism-related projects (Hawkins and Mann 2007: 356); responsibility was ceded to multilateral corporations and NGOs. Meanwhile, some academics argued that tourism creates inauthenticity, museumification, "stress," and sociocultural imbalance akin to imperialism (cf. MacCannell 1976; Nash 1977; Murphy 1985: 1, 3).

While the UN's top-down, economics-heavy focus on tourism was problematic to the peace-making and safeguarding rhetoric of the World Heritage Convention, the Convention found resonances in the UN's Millennium Development Project and the "sustainable tourism" turn of the mid-1990s, which focused on preserving a destination's structural and contextual integrity, facilitating a closer engagements with local stakeholders, fostering a better understanding of the multiplicity of meanings and values attributed to a tourist destination, and ensuring a more equitable distribution of economic and social benefits from tourism development initiatives (Smith and Eadington 1994; Stronza 2001; Telfer 2002; Mbaiwa and Stronza 2009). Revealing a *rapprochement* with the tourism industry, in 1999 UNESCO hosted its first workshop at the International Tourism Exchange (ITB), one of the tourism industry's largest trade fairs, and in 2001 the World Heritage Committee in Helsinki founded what would become the World Heritage Sustainable Tourism Programme, whose aims would be to "engage in dialogue and actions with the tourism industry to determine how the industry may contribute to help safeguard these precious resources" (UNESCO n.d., see 2001: 63). Reflecting the program's mission of "using tourism as a positive force to retain WH site values and to help mitigate site threats," it pursues a threefold strategy of raising awareness, developing partnerships, and providing technical

support to aid the World Heritage Committee, UNESCO field offices, and site managers in assessing and managing tourism-related issues at World Heritage sites. In particular, the World Heritage Centre offers a seven-point "framework for utilizing tourism to benefit site protection" (UNESCO n.d.: 1):

1. Building the capacity of the site management to deal with tourism
2. Training local community members in tourism-related activities so that they can participate and receive tourism's benefits
3. Helping to market these products through their promotion at the local, regional, country, and international levels
4. Raising public awareness and building pride in the World Heritage site with local communities and visitors through a conservation education campaign using a symbolic specie upon which to base a social marketing and public awareness campaign (e.g., a Manta Ray in Komodo National Park, a Toucan in Sian Ka'an Reserve)
5. Using tourism-generated funds to supplement unmet conservation and protection costs at the sites
6. Spreading the lesson learned to other sites and other protected areas
7. Building an increased awareness of World Heritage and its activities and policies in the tourism industry and to the clients of the industry

These statements also reveal an articulated shift from considering tourism as a threat to socio-economic stability to embracing tourism's perceived communicative and awareness-raising abilities. Indeed, in UNESCO's action plan of sustainable tourism development for poverty alleviation in the Sahara Desert – which draws on the cooperation between nation-states, international organizations, travelers, the tourism industry, and local populations (2003a: 5) – UNESCO pointedly reveals its change in position: "There is no contradiction between an economically efficient tourism and an ethical and qualitative tourism, respectful of societies, cultural diversity and environment" (2003a: 2). This sentiment of cooperation with the tourism industry translated into more direct engagement with the UN's World Tourism Organization (UNWTO), whose work on promoting "universally accessible" tourism (UNWTO 2018) had traditionally been considered antithetical to UNESCO's preservation endeavors; in 2015 representatives from the two organizations met in Siem Reap, Cambodia, to discuss a "policy and governance framework necessary to foster a new collaboration model between tourism and culture" (UNWTO 2016: 12). This culminated in the joint issue of the *Siem Reap Declaration on Tourism and Culture* (UNESCO/UNWTO 2015) and a second joint meeting of the two organizations in Oman during the United Nation's Year of Sustainable Tourism for Development in 2017.

Long-Term Objective: Peacemaking

"UNESCO's mission is to contribute to the building of a culture of peace, the eradication of poverty, sustainable development and intercultural dialogue through education, the sciences, culture, communication and information" (UNESCO 2010: 2). To satisfy this peacemaking objective, its World Heritage Convention relies on the prospect of what can be considered *inspired action* – long-term, often subtle changes in the ways in which individuals and groups perceive the meaning and value of not only World Heritage sites but the universality of cultural diversity for which these monuments illustratively stand. In line with some globalization theories' emphasis on individuality over that of collectivities, in which one's imagination negotiates between individuals and "globally defined fields of possibility" (Appadurai 1996: 31; cf. Robertson 1992: 8), UNESCO seems to posit that "peace in the minds of men" can emerge through the reordering of individuals' sense of place; rather than identifying exclusively with sites of local or national interest, individuals may also entertain a "common recognition and identification with the world's shared cultural heritage" as exemplified in these monuments (Di Giovine 2009a: 34) and enacted through collective participation in their preservation and touristic visitation.

While acts of violence include both ethnic cleansing and the destruction of a group's cultural property (UNESCO 1996), activities linking "peace and cooperation" (cf. Sandwith et al. 2001), which are marked by "mutual understanding [and] a plural approach to history," can create a global "culture of peace" (UNESCO 2008a: 90). This notion is made most explicit in UNESCO's (2001) *Universal Declaration of Cultural Diversity*, which, defining culture as the "distinctive spiritual, material, intellectual, and emotional features of a society or group," argued that "respect for the diversity of cultures. . .[and] an awareness of the unity of humankind, and of the development of intercultural exchanges. . .are among the best guarantees of international peace and security" (UNESCO 2002b: 1). Ratified shortly after the September 11 terrorist attacks on New York and Washington, D.C., the Declaration further acknowledges that UNESCO's "specific mandate" within the UN system was to "ensure the preservation and promotion of the fruitful diversity of cultures" (2002b: 1), "as necessary for humankind as biodiversity is for nature" (2002b: 2). Acknowledging that "diversity is the essence of identity" (Matsuura 2002a: 3), UNESCO's then-director general, Koïchiro Matsuura, comments that the Declaration "makes it clear that each individual must acknowledge not only otherness in all its forms but also the plurality of his or her own identity, within societies that are themselves plural" (Matsuura 2002b: i). By simultaneously celebrating the differences that mark human life and yet positing some unanimously recognizable (and valued) universal culture, UNESCO proposes a peaceful world system based on the structural unity of difference – a "culture of cultures" (Sahlins 2000: 488) that Di Giovine terms a world "heritage-scape" (2009a, 2010, 2011). "If a heritage object temporally connects individuals with the socio-spatial milieu from which they came, UNESCO's World Heritage objects are intended to transcend the temporal and spatial situatedness of one culture's heritage claims, ensuring that everyone equally possesses each World Heritage site; rather than basing identities on collective antagonism toward difference, tourists consuming the World Heritage narrative can celebrate and internalize diversity" (Di Giovine 2010: 9).

This ultimate objective is clearly utopian, and while UNESCO and its representatives talk of peacemaking in some of their documents and decrees, it is clear that such a lofty goal is largely implicit and contingent on the successful outcomes of multiple medium-term objectives that are themselves difficult to fulfill. While only time will tell if such a broad plan can work, UNESCO's major challenge – other than ensuring success in the equally idealistic aims of creating sustainable and inclusive preservation and tourism development initiatives – is ensuring that the list remain current and representative of the heritage-scape's audience, which is ever expanding as new populations enjoy greater mobility, global communication, and connectivity. Through the *1994 Global Strategy for a Balanced, Representative and Credible World Heritage List* (UNESCO 1994), the periodic updates to its Operational Guidelines, the passing of associated Conventions and networks protecting other forms of tangible and intangible heritage while increasingly embracing more popular methods of promoting and accessing heritage through tourism, and attempting to expand and diversify the communities it reaches by innovating new organizations such as the Creative Cities Network (see Di Giovine 2015), UNESCO has demonstrated that it is capable of, and willing to make, changes in the forms and meanings of "world heritage" while maintaining its metanarrative of "unity in diversity" (cf. Rössler 2010).

Future Directions

The objectives of UNESCO's World Heritage Convention are ambitious and far-reaching: to ensure the protection of endangered cultural and natural resources, to enhance sustainable development primarily through heritage tourism, and, ultimately, to fulfill UNESCO's "unique mandate," (2001: 1, cf. 2011), established in the Preamble of UNESCO's Constitution, of fostering "peace in the minds of men" (1945: 1). Yet

because UNESCO is an intergovernmental organization that derives its legitimacy from nation-states and its World Heritage program is based on an international convention to which state parties voluntarily adhere, UNESCO has limited ability to affect real policy change in these areas; direct action is limited to creating and disseminating information concerning World Heritage sites in the short term. Instead, UNESCO depends on normative and coercive actions to contribute to safeguarding cultural and natural resources in the medium term, which are believed to lead to inspired action toward tourism development and, ultimately, to peacemaking among global publics in the long term. But since UNESCO relies on the interpretation of its Convention by individual state parties, who have different needs, goals, and understandings of "heritage," unintended consequences often arise. This entry has traced the historical context of UNESCO's logic, examined its various and contingent objectives, and described the major outcomes of each.

"The World Heritage Convention is a noble, vital force in the world, fostering peaceful coexistence and honoring our past in equal measure with our future," remarked Koïchiro Matsuura at UNESCO's celebration in Venice honoring the 30th anniversary of the Convention's ratification (UN News Service 2002). Paying particular attention to the Convention's historical and cultural context, this entry has argued that UNESCO's primary objectives are linked in a complex chain of logic that is contingent upon the successful fulfillment of each short- and medium-term goal: UNESCO's direct act of designating World Heritage sites can increase prestige, thereby fostering preservation and tourism development, which, if implemented correctly, can create a peacemaking understanding of "unity in diversity" in the myriad "minds of men" who interact with, or otherwise consume, these sites and their representations. It is "inevitable" that tourism, preservation, and peacemaking are interlinked, writes Francesco Bandarin, the longtime director of UNESCO's World Heritage Centre in Paris:

> It is an inevitable destiny: the very reasons why a property is chosen for inscription on the World Heritage List are also the reasons why millions of tourists flock to those sites year after year. In fact, the belief that World Heritage sites belong to everyone and should be preserved for future generations is the very principle on which the World Heritage Convention is based. (Pedersen 2002: 3)

Bandarin's quote is telling, for it equates tourism and preservation with the mutual identification with cultures that are not immediately one's own. UNESCO believes it is this celebration, internalization, and preservation of cultural diversity that can ultimately create peace, at least in the minds of men. This is arguably a slow process, one akin to acculturation and which is constantly complicated by inter- and intrastate politics, but only time may tell of its ultimate success.

World Heritage Sites and Education: UNESCO's World Heritage Education Programme

Peter Stone
International Centre for Cultural and Heritage Studies, Newcastle University, Newcastle upon Tyne, UK

Introduction

Article 27 Paragraph 1 of UNESCO's 1972 Convention *Concerning the Protection of the World Cultural and Natural Heritage* states that

> The States Parties to this Convention shall endeavour by all appropriate means, and in particular by educational and information programmes, to strengthen appreciation and respect by their peoples of the cultural and natural heritage defined in Articles 1 and 2 of the Convention.

Given this emphasis, UNESCO has developed the World Heritage Education Programme (WHEP) which has the following objectives:

- To encourage young people to become involved in heritage conservation on a local as well as on a global level
- To promote awareness among young people of the importance of the UNESCO 1972 World Heritage Convention and a better understanding of the interdependence of cultures among young people
- To develop new and effective educational approaches, methods, and materials to introduce/reinforce World Heritage Education in the curricula in the vast majority of UNESCO Member States
- To create a new synergy among educators, heritage experts, environmental specialists, States Parties, development actors, and other stakeholders in the promotion of World Heritage Education on a national and international level

The WHEP, which is regarded by UNESCO as one of its most successful flagship programs for

young people, comprises a number of interrelated projects:

- Development and publication of innovative educational and informational materials, notably the *World Heritage in Young Hands* kit
- Development initiatives for multimedia educational resource material production, including the production of episodes of a cartoon series starring *Patrimonito*, the young World Heritage helper
- Youth Forums and summer camps
- National subregional and regional training seminars for teachers and educators
- Skills development and training courses for young people

For further information concerning the WHEP please see: http://whc.unesco.org/en/wheducation

Definition

The *UNESCO Young People's World Heritage Education Programme* seeks to encourage and enable tomorrow's decision makers to participate in heritage conservation and to respond to the continuing threats facing our heritage.

Key Issues/Current Debates/Future Directions/Examples

Background

Despite education being emphasized in the World Heritage Convention, it was not until 1994 that UNESCO itself began to address this aspect of the Convention in a joint project between the UNESCO World Heritage Centre (WHC) and the UNESCO Associated Schools (ASPnet) in a project entitled *Young People's Participation in World Heritage Preservation and Promotion*.

The idea of an education program relating to World Heritage fitted UNESCO's broader agenda perfectly as it was the lead agency for the United Nations 1988–1997 *World Decade for Cultural Development*. UNESCO had convened a *World Commission on Culture and Development* and documents emphasizing the importance of educational projects, and in particular those stressing cultural diversity, had been circulated to all UNESCO's National Commissions. The Canadian Commission suggested the development of an educational program relating to World Heritage.

Initially, staff from the WHC and ASPnet produced a very simple pack of information outlining the functions of the 1972 Convention and detailing conservation efforts at World Heritage sites that were sent out to any Schools asking for information. Within the year, with this information, projects were produced by schools from 16 Member States and it was clear that there was a real interest in World Heritage education.

In June 1995, a *World Heritage Youth Forum* (WHYF) was organized in Bergen by the Norwegian National Commission for UNESCO in conjunction with the WHC and ASPnet. Young people and their teachers from 25 Member States were present. To raise the profile of the event, the WHYF was timed to coincide with the General Assembly of the *Organisation for World Heritage Cities* (OWHC) and the Director General of UNESCO and city mayors, who were attending the OWHC, were invited to address, and attend parts of, the WHYF.

While the WHYF discussed a wide range of issues relating to World Heritage, two stood out as being particularly urgent: first, the potentially negative impact of tourism and second, the impact of conflict on World Heritage, and other, sites. Tourism pressure on sites was a particular worry for the mayors of some of the cities participating in the OWHC meeting and the issue of conflict had been brought into close focus, given the war in the former Yugoslavia, where the World Heritage city of Dubrovnik had been specifically targeted. An offer by the Mayor of Dubrovnik to host a second WHYF was immediately accepted by those attending the WHYF (ASP net 1995: 23). Participants from other countries also brought examples of their work relating World Heritage to Identity (Egypt), Conservation (Greece), Peace (Senegal), and Nature (New Zealand). A key issue to emerge was that if World Heritage education was to be successful, it needed to be practical:

> Teachers agreed that teaching about the past often remains too theoretical. It has to come alive for young people and be made interesting for them. New approaches in the classroom are needed as well as field visits, excursions and extra-curricular activities. (ASP net 1995: 15)

It was also noted, however, that while such a practical approach was regarded as essential for any WHEP to be successful, that relatively few teachers internationally were comfortable with such an approach to the curriculum.

Following the success of the Bergen WHYF, the WHEP was adopted as a medium-term "Special Project" (1996–2001) by the UNESCO General Conference in November 1995. Work focused on the production and piloting of a WHE kit for teachers and holding of regional youth fora.

As agreed in Bergen, the First European World Heritage Youth Forum was held in Dubrovnik in 1995. Following from the Bergen WHYF, teachers and students from 21 European States Party worked in small groups on draft materials based on six topics:

- The 1972 Convention
- Educational approaches
- World Heritage and the Environment
- World Heritage and Tourism
- World Heritage and a Culture of Peace
- World Heritage and Identity

These draft materials were further refined by a small international advisory group and retested at two more WHYF, in Zimbabwe and China, before a final "experimental" version of the WHE kit was produced in 1998 for testing by ASPnet Schools. In total, 4,000 copies of this experimental version of the kit were produced, 2,500 in English and 1,500 in French. Copies were circulated to all Associated Schools declaring an interest and teachers were asked to complete an enclosed evaluation form. An external evaluation of Young Hands was undertaken in 2000 by the English Heritage Education Service and the information contained in these forms was drawn on in the evaluation. The evaluation was generally positive and, after minor modification, the kit went into full production.

The *World Heritage in Young Hands* kit, aimed primarily at secondary school teachers, has been published in over 30 national language versions. An estimated 57,000 copies have been printed and distributed. The kit has been tested and adapted to national needs and introduced in over 130 Member States of UNESCO through close to 1,000 UNESCO ASPnet Schools. Through the WHC website, the different versions of the kit are gradually being made available free of charge online. UNESCO claims that "at a very conservative estimate, at least a million young students will be reached by all Kit versions" (http://whc.unesco.org/en/wheducation/).

World Heritage Youth Fora

Since the first WHYF in Bergen, some 27 international and regional youth fora have been held with an estimated 1,560 young people participating. Numerous national fora have also been held. These fora provide young people and their teachers with an opportunity to exchange experiences and ideas on how to become involved in heritage conservation and presentation. The fora serve as an inspiration to develop World Heritage educational and participatory activities and help to establish networks for further cooperation at the regional and international level (Fig. 1).

An important development has been the organization of a WHYF in conjunction with the annual World Heritage Committee meeting. One of the exciting highlights of the Forum is meeting members of the World Heritage Committee and its advisory bodies to discuss the Convention and its implementation. A Youth delegation also presents the result of the Youth Forum to the Committee.

Patrimonito: The Young Heritage Guardian

Patrimonito was created in 1995 by a group of Spanish-speaking students during the first WHEF in Bergen. The young students designed Patrimonito on the basis of the World Heritage Emblem which symbolizes the interdependence of cultural and natural sites: The central square is a form created by people and the circle represents nature, the two being intimately linked; the emblem is round like the world and at the same time a symbol of protection. Patrimonito means

World Heritage Sites and Education: UNESCO's World Heritage Education Programme, Fig. 1 Students at the Newcastle World Heritage Education Forum working with a local TV crew on heritage and tourism at Hadrian's Wall. (Credit: Newcastle University)

"small heritage" in Spanish, and the character represents a young heritage guardian and has been widely adopted as the international mascot of the WHEP.

In 2002, a cartoon series entitled *Patrimonito's World Heritage Adventures* was launched where Patrimonito introduces World Heritage sites, the threats they are facing, and proposes solutions to preserve them. Storyboards were chosen following a competition among secondary school pupils to raise their awareness of the importance of World Heritage and their role in preserving it. The competition was organized by UNESCO on the occasion of the celebration of the thirtieth Anniversary of the World Heritage Convention in 2002. The selected storyboards are professionally animated and produced in CD-ROM format for global diffusion to schools and at World Heritage Youth events.

The World Heritage Volunteers Campaign

The World Heritage Volunteers campaign is coordinated by the WHC in cooperation with the Coordinating Committee for International Voluntary Service CCIVS and mobilizes youth NGOs operating in the nonformal sector for World Heritage promotion and preservation through involvement in international voluntary work. Projects are organized by local youth organizations or NGOs which determine the project goals and activities in collaboration with a range of partners (local community, site management, local authorities, and other stakeholders), train work camp leaders, and host international volunteers. Activities themselves are undertaken by young volunteers, aged 18–30 years, coming from different countries. Youth camps generally last between 2 to 4 weeks and accommodate between ten to thirty volunteer participants encouraging young people to play an active role in the promotion and preservation of World Heritage.

Skills Development Training Courses

Skills development training courses relating to the WHEP have trained nearly 1,250 teachers and educators have been trained through nearly 40 seminars and workshops at national, subregional, regional, and international level. Skills development training courses have been provided to over 200 young people.

The Future

The WHEP has now moved into its second phase, seeking to reinforce the involvement of young people in World Heritage preservation, pursuing efforts to integrate World Heritage Education in school curricula, and encouraging communities and States Parties to participate in and promote heritage preservation and intercultural learning.

The WHEP has been funded by a number of extra-budgetary sources including the Norwegian Agency for Development Cooperation (NORAD), the Royal Norwegian Ministry of Foreign Affairs, Rhône-Poulenc, the Dutch Government, the Italian Government, and the World Heritage Fund.

Historical Overview of Syria

Syria is located in the center of the Middle East, which has provided the most ancient civilizations to human history. It is an area with ancient civilizations dating back thousands of years.

Stable human settlements began to appear in the Syrian region in the prehistoric ages. Through the period of historical ages that began in the late fourth millennium BC, Syria was home to many civilizations. It was a zone of conflict for the power and domination of the empires that stabilized and flourished in Mesopotamia, Egypt, Anatolia, and Persia. Syria was the seat of some civilizations such as Ebla, Mari, and others (the end of the third millennium and the beginning of the second millennium BC) and was the seat of civilizations and kingdoms of Amorites, Aramaic, Syriac and others. It was also a home of the Phoenician civilization that spread throughout the Mediterranean coasts and other parts of the coast of the Atlantic Ocean. Additionally, it founded commercial stations that were the beginning of the establishment of civilizations in many areas.

Syria was not the center of empires in the ancient ages, so it was a part of many civilizations through its long ancient history such as Acadians, Babylonians, Assyrians, Chaldeans, Hittites, Hauris, Ancient Egyptians, Hellenistic, and Roman civilizations. In the beginning of the growth of Islamic empire, Damascus became the capital of the Umayyad Caliphate, which was the largest empire in the Islamic history that expanded from middle Asia to the Iberian Peninsula. However, Syria returned to be controlled as a part of successive Islamic kingdoms and caliphate in the Medieval Age, and it was ruled by the Abbasids, Fatimid, Mongols, Tartars, Seljuks, Crusaders, Mamluks, and finally Ottomans. Moreover it was the seat of some kingdoms like Hamadani, Zengid, and Ayyubids. In the first half of the twentieth century, it was dominated by French colonialists who defined its current geographical boundaries. The name of Syria was launched on areas much larger than what is currently known as the "Syrian Arab Republic" (Errico 2013, p. 127). Since 2011 when the war began in Syria, those sites have been listed as World Heritage Sites in Danger.

These sites are (UNESCO):

1. Ancient City of Damascus (1979)
2. Ancient City of Bosra (1980)
3. Site of Palmyra (1980)
4. Ancient City of Aleppo (1986)
5. Crac des Chevaliers and Qal'at Salah El-Din (2006)
6. Ancient Villages of northern Syria (2011)

UNESCO nominates sites in the Tentative World Heritage List, which is an inventory of those properties that each State Party intends to consider for nomination. From Syria there are 12 sites on the tentative list (UNESCO):

7. Norias of Hama (1999)
8. Ugarit (Tell Shamra) (1999)
9. Ebla (Tell Mardikh) (1999)
10. Mari (Tell Hariri) (1999)
11. Dura Europos (1999)
12. Apamea (Afamia) (1999)
13. A desert castle: Qasr Al-Hayr al-Sharqi (1999)
14. Maaloula (1999)
15. Tartus: The Citadel City of the Crusaders (1999)
16. Raqqa-Ràfiqa: The Abbasid city (1999)
17. Arwad Island (1999)
18. Mari and Europos-Dura sites of Euphrates Valley (2011)

The Ancient City of Damascus

It was nominated and listed in 1979 after having achieved five of the ten UNESCO Criterions: I, II, III, IV, and VI.

Damascus is one of the oldest inhabited cities in the world. The archaeological excavations in Tell Al-Ramad on the outskirts of the city show that the area of Damascus has been inhabited before the seventh millennium BC (De Contenson 1985). Damascus as a city with continuous human activity emerged with the presence of the Aramaeans in the third and second millennium BC. It was one of the Decapolis cities in the Hellenistic period. Roman and Hellenistic periods as well as the Byzantine period were very important, and they gave Damascus road plans, which are still visible now. It is known that most of its ancient buildings date back to the Islamic period, especially the period of Ottoman control, which was from the sixteenth century to the beginning of twentieth century.

The city of Damascus has fortifications and fences and seven doors dating back to the Roman period. The doors were renovated and modified, and other doors have been added during later times. The seven Roman doors are Bab Sharki, Bab El Jabia, Bab Touma, Bab Al Jenain, Bab Al-Faradis, Bab Al Sagheer, and Bab Kesan, and the castle in the northwestern corner of the old city, which it may have been constructed in the Seljuk period in the eleventh century AD (OMRAN 2001). It was completed and renovated significantly in the Ayyubid and Mamluk periods after the thirteenth century AD.

The city of Damascus includes many important historical monuments such as:

The Umayyad Mosque that dated back to the beginning of Umayyad period in the eighth century AD. Damascus was the capital of the Umayyad Caliphate, one of the greatest ones in all Islamic history. The Mosque has a large influence coming from Byzantine Basilica shape, like the Basilica of John Batiste where the Mosque built on its ruins.

The city has many ancient *souqs* (markets) and *khanat* (ancient trading complex), now the most of them are important commercial areas, such as Hamidiya Souq, Medhat Pasha Souq, Khan Asaad Pasha (Rihaoui 1975), Souk El Bazouria, Souk El Asrounieh, Souq El Harika, and others.

Old Damascus has many historical residential neighborhoods that are still continuously inhabited. It is noted that some neighborhoods of Damascus were characterized by a specific religious majority and other neighborhoods were inhabited by residents of different faiths. Inside the city walls during its long history the city was multiethnic. Despite some incidents throughout history that led to tragedies and fights as a result of some strife, Damascenes maintained for long historical stages a coexistence of peace, cooperation, and integration among the people in order to

keep their city beautiful and prosperous. Some of the most important neighborhoods inside the city walls of Old Damascus are Bab Sharki, Bab Touma, Al-Qamariyah, Al-Amara, Al-Shaghour, Yahud Quarter (Jewish Quarter) and Al-Amin neighborhood and others outside the city walls such as Al-Salihiya neighborhood, Al-Qanawat neighborhood, etc.

Damascus has many palaces and houses. These houses have a specific type that is called the "Damascene house" or the "Arab house." These types of attached houses have no windows opened on the narrow streets, so it opens onto a courtyard in the middle of the house. Most of them have three levels, which are mainly subterranean basements, ground floors, and first floors and rarely a second floor or more (Burford 1841). The ancient urban fabric of Damascus does not have a European style, which started to appear around the end of the Ottoman period and during French colonization at the beginning of the twentieth century. One of the most beautiful palaces in Damascus is the Al-Azm Palace, built in the eighteenth century by Ottoman ruler As'ad Pasha Al-Azm. It is a beautiful example of Islamic architecture. It was restored and converted to a museum of folk traditions. The palace was built in the style of Al-Ablaq, which uses different colored stones of white, black, yellow, and red. The colors of the stone rows alternate in horizontal lines; this style was developed in the Mamluk and Ottoman periods. Marble, wood, and clay were also used in the construction and decoration. The palace contains many suites and lounges that open onto several inner courtyards rich with trees, water fountains and tiled floors. The Palace is considered one of the most visited historical monuments in the old city of Damascus. The city of Damascus includes many Damascene houses and palaces. We also find many other historical monuments, the most important of which are Beit Al-Akkad, Farhi house, Beit Jabri, Anbar house (one of the beautiful Damascene houses built in the nineteenth century), Bimaristan Nouri (historical hospital), and many more.

The old city of Damascus suffered many damages during the war, according to the official DGAM site in Syria; there are 31 monuments or archaeological sites that have suffered small, medium or large damage. The most important were in the Umayyad Mosque, which had cracks in the southern wall of the mosque and the mosaic overlooking the courtyard, damage in the (southwest) side of the courtyard, fragmentation effects scattered on the columns near the "Al khazneh Dome," and minor damage to the roof in the inner courtyard (DGAM).

In addition, many important historical monuments have had various damages such as As'ad Pasha Azem Palace, Qal'at Damascus (Damascus citadel), the Eliyahu Hanavi Synagogue in Jobar, Yalbugha Mosque, Al-Qabbani Building, Al-Hejaz Railway Station, Al-Qadam Mosque, Essali Shrine, and others (DGAM).

Finally after the Syrian government has regained control on the Old Damascus, it started maintenance and restoration works like the mosaic in the Umayyad Mosque. In October 2018, DGAM reopened the national museum of Damascus for public visits, after having saved more than 300,000 archaeological finds. These finds were brought from the provincial museums of many Syrian cities (Matthiae 2018).

The Ancient City of Bosra

It was first listed as a World Heritage Site in 1980 after having achieved three of the ten UNESCO Criterions: I, III, and VI (UNESCO).

In the Italian encyclopedia *Treccani*, one of its names was "Nova Traiana Alexandrina"; in Turkish it was called "EskiŞam" meaning "Old Damascus" or "Old Sham." The name in Arabic is "Bosra al-Sham," and it is an important historical city located in the south of Syria near the Jordan border and is a part of the Hauran region and near the Arab Mountain. The city has a history dating back to the fourteenth century B.C. Its name occurs in the precious Tell el-Amarna tablets in Egypt, which represent royal correspondence between the Pharaohs and the Phoenician and Amorite kings. But its golden age was in the Roman era when it was the capital of the Roman's Arab Province.

Bosra was an important station on the "Via Nova Traiana" road, which connects Damascus to the Red Sea, passing through the city of Bosra and Philadelphia (Amman) to Aqaba. The city became very important during the reign of Roman Emperor Philip the Arab (Latin: Philippus Arabus, 244–249 AD), who was from the city of Shahba near Bosra, when he declared it a metropolis. We find the city on Philippe's coins in the middle of the third century AD (Mukdad 2007) (Fig. 1). In the Christian period, Bosra remained an important center, when it later became a bishopric and then an archbishopric. During the ascent period of Ghassanid in the sixth century, Bosra formed one of the main Ghassanid centers (Warwick 2000).

Bosra has a special importance in Islamic history, in which the Prophet Muhammad met the Christian monk Bahira in one of his commercial trips in Syria. It was one of the first Byzantine cities to be conquered in the initial phase of Islamic expansion, which became a station on the pilgrimage road to Mecca. It had more importance in Ayyubid and Mamluk periods when it was located near the borderline of the conflict with the Crusaders, and then it declined significantly in the Ottoman period, where very few of its Christian and Muslim populations remained (Fig. 2).

The city is characterized with its archaeological remains dating back to the Roman, Byzantine, and Nabataean periods such as a Roman theater dating back to the reign of Emperor Trajan, the Basilica of the Monk Bahira, the cathedral built in Ghassanid period which was one of the greatest of the East (Warwick 2000), the Church of St. Sergius, several Roman baths, Decumanus Maximus, Triumphal Arch, Tetrapylon, Nabataean arch, and many residential buildings.

World Heritage Syria, Fig. 1 Philippe's coin (Mukdad 2007)

Bosra has many Islamic monuments, which dates back to different periods such as the Ayyubid Citadel that surrounds the Roman theater, which is the most important Islamic monument reserved in the site and was completed in the thirteenth century; the Omari mosque which is one of the oldest mosques in Islamic history; the Mosque of Mabrak el-Naqa (Naqa is the female camel, the place where the camel of the prophet Muhammad had kneeled); Mosque of Fatima; the Gumushtakin Mosque; Hammam Manjak which is a Mamluk bath complex in Damascene style built about 1372 by Manjak, the governor of Damascus (Burns 2009), Birket al-Hajj; and other buildings.

The Site of Palmyra

It was first listed as a World Heritage Site in 1980 after having achieved three of the ten UNESCO Criterions: I, II, and IV (UNESCO).

In Arabic, the city of Palmyra is called "Tadmur"; in Aramaic it is called Tadmur or Tadmurta (meaning marvel) and in Latin called Palmyra. It is an oasis in the Syrian Desert between the Euphrates River and the coastlands of Syria. It contains huge ruins of a great city that was one of the most important cultural centers in the ancient world between the first and third centuries AD. Tadmur was mentioned in the archives of Mary and in Assyrian texts dating back to the beginning of second millennium BC (Seyrig 1951). It became a part of the Roman Empire in the middle of the first century AD as a part of the Roman province of Syria. As a city on the caravan route connecting Persia, India, and China with the Roman Empire, Palmyra has more power and richness. Thus, the art and architecture of Palmyra combines Roman and Greek traditions with local and Persian traditions. It is a special and

World Heritage Syria, Fig. 2 Map of Bosra archaeological site (Burns 2009)

distinctive case of Hellenistic and Roman art (Balty 1996).

The city of Palmyra has 6 km semioval defensive walls, surrounding all of the city's buildings such as official, religious, cultural, market, and residential neighborhoods. The Palmyrenes were mixed from Amorites and then Aramaic and Arab tribes, the most famous of which were Komare, Mattabol, and Ma'zin. The city also had a Jewish community. The inhabitants of the city spoke Palmyrene, a dialect of Aramaic, used for writing the Palmyrene alphabet. They also used less Greek language in commercial and diplomatic communications.

Odaenathus and Zenobia: Odaenathus was one of the most famous kings of Palmyra; he defeated the Persian king Sabor I, so he got the title "Imperator Totius Orientis" from Roman Emperor Galianos and became the Governor of the East.

In the Byzantine Era, it became a Christian city, and it was reduced to a small town in the Islamic period. Palmyra in its Arabic name Tadmur was mentioned in the books of Arabic historians and travelers such as Yaqoot al-Hamwi in the thirteenth century AD, Ibn Alshehneh in the fifteenth century AD (Al-Bounni 1972), Al-Bakri, and others; they described it as an existing city with a great history and monuments. It was re-illuminated by the European travelers in the seventeenth and eighteenth centuries. In the twentieth century, the excavations revealed many

of its archaeological treasures and are still hiding more.

The most important of Palmyra monuments are Great Colonnade of Palmyra, Tetrapylon, Triumphal Arch, Roman theater, Agora, and Diocletian Camp.

The city had many temples for its various inhabitants who worshiped local Semitic deities and Mesopotamian and Arab gods. The most important temples are the Temple of Bel and Temple of Baalshamin (Collart 1957). Outside the city walls extends the large Valley of Tombs that is about 1 km long and includes a big number of various types of tombs. The more monumental one is tower tombs; the more important one is the Tower of Elahbel (Al-Bounni et al. 1979).

The Great Colonnade is the main axe of the ancient city, about 1100 m long and built in the second and third centuries AD (Segal 1997).

The Temple of Bel: As a pantheon of the Palmyrene gods, it was the most important religious building dedicated to Bel (the Akkadian Babylonian god). At the same time, Palmyrenes worship other gods in this temple such as Yarhibol (the sun god) and Aglibol (the lunar god) (Teixidor 1979).

The Roman Theater: It has a small stadium consisting of about 13 rows, a semicircular building with limestone, built in the first half of the second century AD. It has been buried under sand, and then it was found in the excavations carried out in 1952.

In 2015 during the Syrian civil war, ISIS was conquest to the city of Palmyra, when they destroyed the most important monuments of Palmyra, such as Temple of Bel, Temple of Baalshamin, Triumphal Arch, Tower Tombs of Elahbel, Tetrapylon, and others. In addition, the site was damaged from the battles that carried out there. In August 18, 2015, in the city of Palmyra, ISIS have killed in a savage way the archaeologist Khaled al-Asaad, who was the curator of the site and museums of Palmira for a long time, and he spent his life in work, exploration, and research at the Palmyra site. In 2017 the Syrian Army has liberated the city from ISIS.

Ancient City of Aleppo

It was first listed as a World Heritage Site in 1986 after having achieved two of the ten UNESCO Criterions: III and IV (UNESCO).

Aleppo is located in northern Syria, between the Mediterranean coast and the Euphrates. It grew up on a calcareous plateau that gave Aleppo the stone as a main building material in the city, which preserved many historical monuments in good condition.

The city of Aleppo is one of the oldest cities in the world, which has been an important center without interruption for at least 4500 years; it was mentioned with the name (Khalab) in Ebla texts from the late third millennium BC (Archi 1999). Archaeological excavations at Aleppo Citadel revealed the Temple of Hadad (the Storm God), which date back to the second half of the second millennium BC (Burns 2016). Through a long history, many civilizations settled in Aleppo: the Akkadian and Eblaite were the first; then the Amorites had established the kingdom of Yamhad in Aleppo and its region; then the Hittite, Mitanni, Assyrian, Chaldean, Achaemenid, and the obvious presence of the Hellenistic Era where Seleucus Nicator established the Hellenic city of Beroea in the site in the third century BC; and then the Roman and Byzantine civilizations (Bryce 2014); the city contains few architectural and archaeological remains that belong to those civilizations. After, it began the Islamic period, starting with Rashidun Caliphate, Umayyad Caliphate, Abbasids Caliphate, Hamdanids, Seljuq, Zengids, Ayyubids, Mongols, Timurid, Mamluk, and Ottomans (Gaube 2007). Finally, the French mandate was in the first half of twentieth century.

The urban fabric of the Ancient City of Aleppo (Fig. 3) covers an area of about 4 km^2; it has a rich ethnic variety, so it has many important religious buildings belonging to Islam, Christianity, Judaism, and others. But mostly ancient Aleppo demonstrates the urban structure of the Islamic city, where the main part of it dates back to Ottoman period from 1517 to 1918. Hellenistic

World Heritage Syria, Fig. 3 The Ancient City of Aleppo inside and outside walls (Windelberg 2001)

and Roman urban style is presented clearly in the area of Jallum neighborhood that contains the Al-Madina Souq (the old markets) and caravanserais, the Great Mosque; this area extends from the west side of the Citadel to Bab Antakeya (the Door of Antioch) (Gaube 2007). In the heart of the walled city, we see the formidable citadel; it is located on a high artificial hill that has been grown through a long history. Many historical neighborhoods grew out of the city walls between sixteenth and twentieth centuries (Watenpaugh 2004). The Old City of Aleppo houses more than 106,000 residents in many ancient quarters (Windelberg 2001), which are located inside and outside the city walls. Each one was characterized by the religious and ethnic characteristics of its inhabitants (Raymond 1985), and some others are ethnically mixed. The most important quarters and urban elements of old city are:

The doors: There have been known 12 doors in the walls of the city, 5 of which are still existent: Bab al-Hadid, Bab al-Maqam, Bab Qinnasrin, Bab Antakeya, and Bab al-Nasr; the other doors are ruined: Bab al-Ahmar, Bab al-Nairab, Bab al-Jinan, Bab al-Faraj (Gaube 2007), Bab Al-Hayyat, Bab Al-Faradis, and Bab Al-Salama (Hadjar 2005).

The quarters: Inside and outside the city walls – Aqabeh, Bayadah, Farafira, Jalloum, Al-Qasileh, Aghyol, Almaji, Fardos, Hazzazeh, Kallaseh, Qadi Askar, Qarleq, Al Jdaideh, etc. (Hadjar 2005).

The most significant historic buildings of the Ancient City of Aleppo: Aleppo Citadel, Bimaristan Arghun al-Kamili, Al-Shibani Church-School, Khanqah al-Farafira, and others.

Places of worship: Great Mosque, Mar Assia al-Hakim Church Syrian Catholic, the Central Synagogue of Aleppo or al-Bandara synagogue, Forty Martyrs Armenian Cathedral, Al-Shuaibiyah Mosque, etc.

Madrasas: Al-Muqaddamiyah, Al-Halawiyah, Al-Firdaws, Al-Zahiriyah, Al-Kamiliyah, etc.

Traditional houses: Junblatt Palace, Beit Ghazaleh, Beit Basile, Beit Marrash, Beit Achiqbash, Beit Dallal, etc.

Traditional bathes (Hammam): Hammam Yalbugha, Hammam al-Sultan, Hammam al-Nahhasin, Hammam al-Bayadah, Hammam al-Jawhary, Hammam Bahram Pasha, Hammam Bab al-Ahmar, etc. (Hadjar 2005).

Since 2012 when the disaster in Aleppo actually started, many associations and organizations started ideas and projects aiming to the conservation and restoration of Syrian cities, mainly the city of Aleppo and its ancient center.

Crac Des Chevaliers and Qal'At Salah El-Din

It was first listed as a World Heritage Site in 2006 after having achieved two of the ten UNESCO Criterions: II and IV (UNESCO).

These two citadels are the most important example of Byzantine, Crusader, Ayyubid, and Mamluk military buildings in the Levant, illustrating the exchange of influences and the documentation of the development of fortified architecture in the Near East during these periods (UNESCO). The distance between them is approximately 95 km. The two were built out of cities on the heights of the Syrian coastal mountains. There were points of conflict and wars between the Ayyubids and then the Mamluks with the Crusader kingdoms that are established in the Levant coast during approximately all twelfth and thirteenth centuries. Most of their architectural elements date back to the Crusader and Byzantine periods, and quite a few elements were added in later periods during the reign of the Ayyubids and Mamluks.

Crac Des Chevaliers

In early eleventh century AD when the site of the citadel was a camp of Kurdish garrison established by the ruler of Homs, the citadel had been named "Hisn Al-Akrad" (the castle of the Kurds) (Kennedy 1994). It was built on the top of a mountain rising approximately 660 m above sea level and overlooking an area called "Fathet Homs" (gap of Homs) that is a relatively low area of the coast mountains of Levant, which

provides easy connection between the city of Homs in Syrian inland and the cities of Tripoli and Tartous on the coast. It has a strategic location that monitors traffic communication between the inland and coast areas (Kennedy 1994). The Crusaders captured the citadel in 1110 AD (Kenneth 1977). It was granted by the Count of Tripoli Raymond II to the Hospitallers. It was built by the Hospitallers Order of Saint John of Jerusalem from 1142 to 1271, with further construction by the Mamluks in the late thirteenth century (UNESCO).

In 1271 the Mamluk Sultan Baybars captured the castle after a siege lasted more than a month. After the castle was damaged as a result of its bombardment, it was restored and improved in the thirteenth and early fourteenth centuries by the Mamluks who used it as a base for their military operations (Kenneth 1977). After the conflict with Crusaders ended, the castle lost its strategic importance and was abandoned. In the nineteenth century, the villagers occupied the site and lived inside it until the French mandate. The castle is located on a Trapezoidal basaltic plain separated from the mountain on the southern side by an industrial trench. The castle is divided into two integrated defensive zones. The upper castle, built on a rocky hill in the center of the site, is organized around a central patio space and has a double trapezoidal wall. It includes the religious architectural complex containing a small chapel, and the fortified building on the south side was the residence for Hospitallers (DGAM).

Qal'at Salah El-Din

It is located near the city of Al-Hafah and about 30 km east of Lattakia on the coastal mountain at a height of 440 m above sea level, built on a narrow ridge that has a triangular shape whose head at the west direction. At the north and south, there are two deep valleys (Fig. 4). The site was separated from the east by a deep trench dug in the Byzantine period, the architect left a pillar in its center to support a movable bridge. The citadel was called the "Saone Citadel" in Arabic "Sahyun Citadel," which was replaced with the name of "Salah El-Din Citadel" in 1957. Arab historians such as Yahya al-Antaki and Ibn al-Qalanisi mentioned that it was affiliated to the Hamdani and its ruler was "Raqtash the Turkish" in 975 AD, but no traces of that period were found (Saada 1967). When Byzantine Emperor John Tzimiskes conquered Syria, he took the site in 975 AD. It continued under Byzantine domination until the Crusaders captured it in 1108, when they conquered all Lattakia area (Kennedy 1994).

The Byzantine buildings were concentrated in the upper courtyard, which is located in the

World Heritage Syria, Fig. 4 The map of Qal'at Salah El-Din

eastern part of the plateau, which includes the largest number of buildings of military, civil, and religious use. This area is the most difficult to understand in terms of architectural organization and construction stages due to overlapping works and similarities in the techniques and the problem of repeated reuse.

The western part of the ridge is separated from the upper courtyard by the beginning of a ditch. Its walls are equipped with four rectangular towers and a circular tower which were built during the Crusader period.

After the siege of several days and being bombarded with catapults, in 1188 Saladin conquered the citadel (Saada 1967).

Because of the Syrian conflict, the Salah El-Din Citadel had a few damages, but Crac Des Chevaliers have had more: damage to the tower due to clashes, the southern towers, the Knights Tower, the mosque, the entrance tower, the external façades of the northern side, the stable overlooking the moat, King Al-Zahir Baybars Tower, the Knights Hall, the pathway leading to the kitchen, and the eastern tower opposite the Knights Tower (DGAM). Since March 2014, the Syrian government has regained control on the site and began emergency maintenance and documentation (UNESCO).

Ancient Villages of Northern Syria

It was first listed as a World Heritage Site in 2011 after having achieved three of the ten UNESCO Criterions: III, IV, and V (UNESCO).

They are also called the "Dead Cities" or the "Forgotten Cities." There are around 40 villages that were grouped into 8 archaeological parks (Fig. 5), located on the calcareous plateau in northern Syria within the governorates of Aleppo and Idleb. They date back to the Roman period and most of them to the Byzantine period. These sites were built between the first and seventh century AD. Their development ceased and declined at the end of the third century AD to flourish again between the end of the fourth century and the end of the sixth century, and then they were abandoned between the eighth and tenth

World Heritage Syria, Fig. 5 Map showing the eight groups of old villages north of Syria

World Heritage Syria, Fig. 6 Map showing the first, second, and third groups of old villages north of Syria

centuries when the farmers gradually left their villages toward the nearby plains (Tatt 1990). There are many well-preserved historical remains including pagan temples, churches, Christian sanctuaries, funerary monuments, baths, public buildings, and economic buildings. These ruins integrated in their natural environment form a series of unique and exceptional cultural landscapes.

They provide an example of rural life in the Byzantine period and give us knowledge of the development of Christianity in the East. They include ruins of many monuments and important Byzantine churches such as the Church of Saint Simeon Stylites; in the archaeological site of Brad, there is the tomb of St. Maron; he was the founder of the Maronite Church, Churches of Sheikh Suleiman village, Mushabbak Basilica, Qalb Loze Basilica, Serjilla ruins, the pyramid tomb in Bara, and others (DGAM 2010).

There are some damages of the sites of Ancient Villages since the start of Syrian conflict in 2011. These damages come from illegal excavations, destruction, and damage due to the armed conflict, damage of historic buildings due to the use of ancient stones as building material, illegal constructions, use of the sites by internally displaced persons and armed groups, and finally quarrying (UNESCO).

The first group of villages is area of 3700 ha the Archaeological Park "Jebel Sem'an 1" contains six sites: Qal'atSem'an, Deir Sem'an, Refadé, Sittar-Roum, Qatura, and Sheikh Barakat (Fig. 6).

The second group of villages is area of 2760 ha; the Archaeological Park "Jebel Sem'an 2" contains five sites: KafrNabo, Kalota, Kharab Shams, BorjHaydar, and Brad (Fig. 6).

The third group of villages is area of 380 ha; the Archaeological Park "Jebel Sem'an 3" contains three sites: Batouta, Sinkhar, and Sheikh Suleiman (Fig. 6).

The fourth group of villages is area of 3200 ha; the Archaeological Park "Jebel Zawiyé 1" contains ten sites: al-Bara, Wadi Martaoun, Mujleya, Btirsa, Bshilla, Ba'uda, Dallozé, Serjilla, Shinshara, and Rabi'a (Fig. 7).

The fifth group of villages is area of 530 ha; the Archaeological Park "Jebel Zawiyé 2" contains two sites: Ruweiha and Jeradé (Fig. 7).

The sixth group of villages is area of 460 ha; the Archaeological Park "Jebel al-A'la" contains three sites: QalbLozé, Kfeir, and Qirqbizé (Fig. 8).

World Heritage Syria, Fig. 7 Map showing the fourth and fifth groups of old villages north of Syria

World Heritage Syria, Fig. 8 Map showing the sixth and seventh groups of old villages north of Syria

The seventh group of villages is area of 580 ha; the Archaeological Park "Jebel Barisha" contains four sites: DarQita, Deirouné, Kherbetal-Khatib, and Baqirha (Fig. 8).

The eighth group is area of 680 ha. Archaeological Park "Jebel Wastani" contains three sites: Benasra, al-Fassouq, KafrAqareb (Fig. 9).

World Monuments Fund (WMF)

Lisa Ackerman[1,2] and Gaetano Palumbo[3]
[1]Executive Director, Columbus Citizens Foundation, New York, NY, USA
[2]Pratt Institute School of Architecture, New York, NY, USA
[3]World Monuments Fund, New York, NY, USA

Introduction

World Monuments Fund (WMF), with headquarters in New York, is the leading independent organization devoted to saving important cultural heritage sites around the world. For over 45 years, working in more than 100 countries, WMF's highly skilled experts have applied proven and effective techniques to the preservation of important architectural and cultural heritage sites. Through partnerships with local communities, funders, and governments, the organization inspires an enduring commitment to stewardship for future generations. WMF projects span the history of human civilization, from the earliest known cultures to the recent past.

Key Issues/Current Debates/Future Directions/Examples

WMF's Program Areas

The organization's work encompasses five core program areas.

Cultural Legacy: WMF has a long history of protecting monuments that represent a cultural era or a particular period of artistic expression, such

as the moai of Easter Island (Charola 1994); sites in Venice, Italy (Kaley 1980); the Taj Mahal, in Agra, India; or the Qianlong Garden, in Beijing's fabled Forbidden City. These are sites of universal importance, for which the organization raises funds, brings together support, and works toward long-term, sustainable preservation. WMF's conservation work in the Qianlong Garden is undertaken in full cooperation with the Palace Museum. The project is notable not only for the fine craftsmanship of the conservators, but the program has resulted in a great flowering of opportunities strengthening the ability of conservation in the Qianlong Garden to serve as a springboard for international exchange of ideas through colloquia; specialized conservation training for specific materials; publications; and the development of an exhibition, *The Emperor's Private Paradise*, which allowed the public to understand the context of the objects created for this extraordinary imperial retreat (Berliner 2010).

Capacity Building: In addition to working on physical restoration, WMF helps local communities build the governmental, financial, and technical infrastructures needed to preserve and sustain their heritage. One of WMF's most successful capacity-building programs is at the vast temple complex of Angkor, in Cambodia, where the organization has been working for 20 years. Conservation and capacity building activities have resulted in several important publications. Most notably a monograph on Preah Khan Monastic Complex (see Coe and Stubbs 2011). For Phnom Bakheng, the oldest temple at Angkor, publications have resulted that provide site management plans, environment surveys, and artistic and historical interpretations (Chermayeff et al. 2006). Another capacity-building program is its Iraq's Cultural heritage Program, which has the aim to assist the State Board of Antiquities and Heritage in rebuilding its capacities as steward of Iraq's rich archaeological and historic heritage. This program has included several courses on site documentation, condition assessment, and site management planning organized with the Getty Conservation Institute, and continues today with the development of a web-GIS of Iraq's known cultural heritage sites (Palumbo et al. 2009). In Central and South America, WMF has promoted various capacity-building programs, centered on national conservation policies (Horton et al. 2010) or specific groups of monuments (Charola and Magadán 2009).

Advocacy: Through its advocacy programs, WMF speaks out in support of architectural and cultural heritage around the globe (Giurescu 1989; Conference Abstracts 2002; Chusid 2011; Haney et al. 2011). Its signature advocacy tool is the World Monuments Watch, a biennial list of endangered sites. Launched in 1996, the World Monuments Watch is a powerful call to global action on behalf of sites needing immediate help. Hundreds of Watch sites have been preserved or are now out of danger. Special advocacy themes have emerged from the Watch through which WMF has focused on areas that deserve increased public attention. Modernism at Risk became the vehicle through which WMF communicated to the public the increasing alarm by many that icons of twentieth century architectural and design heritage were being lost. Sustainable Tourism is another vehicle for WMF to deliver a message emphasizing the fragility of sites and the need for sensible approaches to assist the public in enjoying a wide range of cultural sites. Too often, visitors are not provided with sufficient information to understand that there can be many historic places to visit and not only the most famous sites. Sustainable Tourism encourages greater exploration of the cultural riches to be encountered around the world and ways that the visitor experience can be improved and travelers can become engaged in the preservation process.

Education and Training: WMF takes a multi-layered approach to education, promoting the exchange of information among professionals, educating the public, and training craftspeople in both lost arts and modern standards. Through site interpretation, international symposia, and field schools, such as the ones held in New Orleans in the aftermath of Hurricane Katrina, WMF helps to ensure that heritage preservation remains a vital

field. WMF has provided opportunities for high school students in Newburgh, New York, to work on a historic structure through summer field schools, but the project also became a portal to learn about the history of Newburgh, a city once famed for its role in the American Revolution. WMF facilitates graduate and postgraduate research projects, which have allowed emerging preservation professionals to work on sites as varied as the landscape connecting Lednice and Valtice estates in the Czech Republic, Horace Walpole's Strawberry Hill in the UK, the Gertrude Vanderbilt Whitney Studio in New York City, and the historic urban centers and colonial churches of the Colca Valley in Peru.

Disaster Recovery: WMF's work in disaster recovery has ranged from its response to the Venice flood over 40 years ago to its recent work in Iraq and Haiti. While it cannot plan in advance for damage wrought by natural or man-made disasters, WMF is nonetheless ready to step in wherever possible, providing rapid-response experts, damage assessments, and assistance in conservation planning and implementation. Notable among WMF's projects are the complete restoration of the Abbey of San Clemente a Casauria after the 2009 earthquake in Abruzzo, Italy; a series of missions to Haiti in 2010, following the earthquake, which led to the publication on the Gingerbread Houses of Port-au-Prince to assist homeowners and policymakers in developing alternatives to demolition (Langenbach et al. 2010); and participation in the Lower Manhattan Emergency Preservation Fund after the destruction of the World Trade Center.

WMF and Archaeology

WMF's activities span the full breadth of human artistic achievement from the earliest settlements of antiquity through the twentieth century. WMF's concern is to conserve sites of cultural merit and increase public awareness of the significance of these sites that embody cultural traditions giving special character to historic places cherished by local residents and international visitors. While WMF does not have a formal program in archaeology, nor does the organization engage in active archaeological exploration, archaeological investigation can be an essential element in the conservation process. Additionally, the presentation of archaeological sites and interpretation for the public has figured prominently in many WMF projects. These activities have ranged from the implementation of complex documentation and assessment projects to the design and installation of protective shelters, and from the development of site management plans to the creation of visitor itineraries and interpretive materials. Of special note is WMF's work at Babylon in Iraq, where WMF is working closely with the State Board of Antiquities and Heritage to complete a site management plan and conserve key architectural structures on the site. WMF is also working in Bulla Regia, Tunisia, in a complex project that involves surveys, documentation, management planning, interpretation and site presentation, conservation, and sheltering, all conducted in cooperation with the Institut National du Patrimoine of Tunisia, providing training opportunities for its staff. Documentation is an essential component of all WMF projects, which benefit from a vast array of tools and technology available in the field today.

When appropriate and feasible, 3D laser scanning has been employed as part of the documentation process at WMF project sites. At Lalibela, in Ethiopia, WMF and University of Cape Town have completed one of the largest laser scanning projects conducted on a cultural heritage site, with the resulting data now used by the architects and conservators to map conditions and develop their conservation plans. WMF has employed laser scanning at numerous sites around the world and continues to employ the technology in coordination with other documentation efforts to assure the most accurate data possible at project sites.

At the temple of Amenhotep III in Luxor, Egypt, WMF assists the mission directed by Hourig Sourouzian in an ambitious project that sees archaeological excavation and conservation proceed hand in hand to reveal and eventually reerect parts of the largest Egyptian temple known, including the colossi of the second and third pylons of the temple.

Conclusions

WMF is committed to disseminating information to professional colleagues and the interested public. WMF staff members and consultants regularly present information on projects at professional workshops, conferences, and colloquia. All WMF's publications have been digitized and made freely available on its website, www.wmf.org. Further, information on more than 300 projects and all past World Monuments Watch sites can be found on www.wmf.org.

World-Systems Analysis

Alf Hornborg
Human Ecology Division, Lund University, Lund, Sweden

Introduction

From its beginnings, archaeology has discussed the pervasive role of regional and interregional interaction in accounting for local records of prehistoric society. Because field archaeologists are generally confined to local excavation sites, their various understandings of the nature of such supra-local connections and influences have been contested and often speculative. Postulations of migration, diffusion, and long-distance

exchange as explanations of widespread similarities in the material record have thus generated voluminous debate. Concepts such as "interaction spheres" have been resorted to as a way of acknowledging extensive areas united by exchange in prehistory but often without suggesting a specific sociocultural or institutional framework that may have generated this exchange and without identifying its consequences for the populations involved. The recognition that much prehistoric social organization was regional or even interregional in scope has prompted archaeologists to turn to social sciences such as sociology, anthropology, political science, and economic history for models of long-distance societal interaction. Following Wallerstein's (1974) proposal for a "world-system" analysis of sixteenth-century exchange in early capitalist Europe, several researchers from different disciplines have suggested that a similar model should be used to interpret archaeological indications of long-distance exchange in precapitalist societies. Wallerstein's and other such early "global" models (e.g., Ekholm and Friedman 1979) emerged from a yet earlier "dependency theory" originally articulated by Andre Gunder Frank to account for the polarization of developed and "underdeveloped" nations in the modern world. Much of the discussion regarding the use of world-system analysis in archaeology has thus predictably concerned the extent to which assumptions about social processes in the modern world can be applied to prehistoric societies.

Definition

The central argument of the world-systems approach is that the specific trajectories of local, territorially bounded, or culturally homogeneous societies will largely be the result of much wider and less easily mapped fields of interaction. In Wallerstein's (1974) study, the economic development of individual nations in sixteenth-century Europe is explained in terms of an international division of labor within and beyond Europe. For Wallerstein, this sixteenth-century world-system comprised a "core," a "periphery," and an intermediate buffer zone or "semi-periphery." The core is the main locus of capital accumulation, based on an "unequal exchange" of its manufactured products for raw materials from its impoverished periphery. This model clearly draws on Frank's use of the concepts of "metropole" and "satellite" in dependency theory. Wallerstein emphasized the trade in bulk goods such as food and fuel (with low value-to-weight ratio) in generating core-periphery polarities and suggested that trade-in "preciosities" (prestige goods or luxuries) would not in itself have such systemic effects. For this and other reasons, Wallerstein has discouraged the application of world-system models to precapitalist contexts, except when dealing with politically unified "world empires." Others, such as Schneider (1977), while seeking to promote the world-systems approach to precapitalist societies, including its emphasis on regional inequalities, argue that precapitalist "world economies" were often based precisely on the exchange of preciosities.

The exchange of exotic prestige goods controlled by social elites is indeed a familiar theme in archaeological research and often appears to be geared to regional asymmetries. Several edited collections (Rowlands et al. 1987; Champion 1989; Chase-Dunn and Hall 1991) focus on relations between "centers" and "peripheries" in ancient societies, discussing the extent to which economic, political, or cultural asymmetries can be detected in the archaeological record. Chase-Dunn and Hall distinguish between core-periphery "differentiation" and core-periphery "hierarchy," observing that not all seemingly asymmetric relations in precapitalist world-systems entail exploitation or political domination. They also propose that a world-system perspective can be applied to different kinds of supra-local interaction networks with different geographical extent, ranging from far-reaching exchanges of information and prestige goods through a more restricted zone of regular military interaction to a spatially even more circumscribed domain of bulk-goods exchange. The boundaries of such networks are conceptualized as thresholds, where the density of interactions sharply decreases. Such a wider definition of "world-

systems" would accommodate a variety of modes of long-distance interaction in prehistory, and several prominent archaeologists have adopted the term in their analyses of such interaction, both in the ancient Old World and in the pre-Columbian New World. Edited collections have appeared which discuss the relations between the "world-system" terminology and similar concepts such as "civilizations" (Sanderson 1995) and "interregional interaction" (Schortman and Urban 1992). The objection has been raised, however, that a looser, more inclusive definition of "world-system" risks making the category amorphous and analytically useless.

Key Issues

The usefulness of applying the concept of "world-system" to non-capitalist societies has been the subject of much discussion. For several of its advocates, a criterion by which a "world-system" can be identified is the occurrence of correlations between cycles of growth and decline in widely separate areas. Frank thus based his proposal of a singular Bronze Age world system spanning much of Afro-Eurasia on what he and Gills perceived as largely calibrated cycles of expansion and contraction in different parts of the Old World between 1700 BCE and CE 1700 (cf. Frank and Gills 1993). Although the details of this argument have been contested, there appears to be some agreement that several early Old World civilizations were to some extent interconnected and their trajectories sometimes calibrated (cf. Chase-Dunn and Hall 1997; Hornborg and Crumley 2007).

Several archaeologists have proposed significant modifications of the Wallersteinian "world-system" concept in order to make it applicable to prehistoric societies. Most of the advantages and problems of applying world-system analysis to archaeology are addressed in a collection edited by Kardulias (1999). Particularly problematic are questions regarding how world-systems are to be delineated in geographical space and whether long-distance interdependencies also imply interregional inequalities, hegemony, and underdevelopment. The inclusion of prestige-goods exchange networks in the category "world-systems" suggests that, in these systems, interregional polarizations of power, while often manifest, are not immediately implied by the nature of the interaction itself. Other regularities, such as the tendency of new centers of accumulation to develop on the frontiers or margins of earlier systems, contributing to their decline, appear to recur in both modern and premodern contexts. A fundamental constraint of most world-systems is the tendency of a core's capacity to control its hinterland to diminish with distance. Much as von Thünen showed already in 1826, for instance, the reason why prestige-goods exchange reaches farther than bulk-goods exchange in traditional societies is a matter of logistics and transport costs. Such dynamics have undoubtedly limited the interregional exercise of power, particularly in premodern settings (cf. Stein 1999). With various modifications and criticisms taken into account, the world-systems approach nevertheless continues to generate important transdisciplinary discussions on the prospects of writing world history over the very long term (cf. Denemark et al. 2000).

Current Debates

In recent years, the world-systems perspective has been criticized for reproducing a Eurocentric perception of people in the "periphery" as passive victims of expansion rather than as active agents negotiating their relation to the "core" in their own terms (cf. Stein 2002). While it is certainly justified to acknowledge the agency of the periphery in contributing to the particularities of core-periphery relations, it would be unfortunate if such a concession to "bottom-up" perspectives should obscure the historical incentives of colonial and imperial power centers. The world-system perspective is fundamentally materialist in that central concepts such as "unequal exchange" and "exploitation" are understood as objective, material phenomena. To be sure, cultural processes of ethnogenesis and identity formation in world-systems are as important and worthy of study as their material metabolism, but

the inequalities which polarize "cores" and "peripheries" cannot be reduced entirely to cultural or ideological constructions. The world-system approach as developed by Frank and Wallerstein is ultimately concerned with the structures of long-distance exchange which contribute to capital accumulation in the core and impoverishment in the periphery. If this model is to maintain its relevance in both modern and premodern contexts, the sense in which exchange is "unequal," "asymmetric," and "exploitative" needs to be specified. Otherwise, the model will be reducible to a tautological definition of "core" as the locus of accumulation and "accumulation" as what occurs in the core. In the modern world economy, the exchange of manufactures from the core for raw materials from the periphery implies a recursive, net transfer of productive potential (negative entropy) from the periphery and a continuous gain in purchasing power in the core. Thus defined, unequal exchange is a process of social reproduction that systematically reinforces capital accumulation in the core and relative impoverishment in the periphery. Although similar structures of exchange may have characterized a number of premodern world-systems, this should be investigated empirically for each case. There are obviously many cases where no such systematic exchange of manufactures for raw materials can be identified.

Against this background, the most urgent challenge for world-systems research is to develop analytically rigorous definitions of the processes of "capital accumulation" and "unequal exchange," which are so frequently referred to but remain conspicuously under-theorized in the world-system literature. Wallerstein's explicit references to Arghiri Emmanuel's calculations of the unequal exchange of embodied labor time suggest that labor is the metric he would resort to in a definition, but this basically Marxian framework needs to be complemented with calculations of the unequal exchange of embodied natural space, i.e., land. Although generally more or less impossible to estimate in prehistoric contexts, the flows of labor time and natural space embodied in goods and services can occasionally be reconstructed from historical and archaeological data on the metabolism of empires such as Rome or the Inca. In widening the concept of "world-system" to accommodate premodern societies, it will thus be necessary to also widen the concepts of "unequal exchange" and "capital accumulation." If the monumental architecture of imperial Rome and the agricultural terraces of the Inca can be recognized as "capital" that was as productive in their respective contexts as were textile factories in nineteenth-century Britain, it should be relevant to approximately estimate the net quantities of labor time and natural resources that were invested in their production. Such calculations would make it reasonable to posit the occurrence of "unequal exchange" and "capital accumulation" in ancient world-systems.

While perhaps feasible in the case of modern world economies and some premodern world empires, calculations of the unequal exchange of embodied labor and land would be unlikely to illuminate core-periphery asymmetries in prestige-good systems, where elites exchange exotic products that are strategically used to mobilize their local followers. An alternative approach would be to estimate discrepancies between the "catalytic" potential of different prestige goods circulated in such separate but interacting local economies, measured in terms of the labor time that they are able to mobilize, relative to the input of labor time invested in their production and transport. Such discrepancies, when related to the rates at which the different kinds of prestige goods are exchanged, should increase our understanding of the systemic logic of core-periphery asymmetries in premodern societies.

Worsaae, Jens Jacob Asmussen

Poul-Otto Nielsen
The National Museum, Copenhagen, Denmark

W

Basic Biographical Information

Jens Jacob Asmussen Worsaae (1821–1885) (Fig. 1) was a Danish archaeologist and museum director, who created the basis for the development of prehistoric archaeology as a scientific

Worsaae, Jens Jacob Asmussen, Fig. 1 J.J.A. Worsaae (1821–1885). (After a drawing by August Jerndorff)

discipline in the mid-nineteenth century. He was born in Vejle, Jutland, as son of the County Steward. In 1836 he came to Copenhagen and worked until 1843 as a volunteer at the Royal Museum for Nordic Antiquities under the leadership of Christian Jürgensen Thomsen. He studied law and theology at the University of Copenhagen but did not graduate. Instead he became occupied with archaeology and in 1843 came under the patronage of the Danish king Christian VIII, who urged him to write a survey of Danish prehistory. The King also contributed financially to Worsaae's travels and studies in Norway, Sweden, and Germany (1842–1845) and in the British Isles (1846–1847). In 1847 he was appointed Inspector for the Conservation of Antiquarian Monuments. He obtained the title of professor in 1855 and was the first to give lectures on prehistoric archaeology at the University of Copenhagen. In 1858 he became Inspector, from 1865 Director, of The Danish Royal Collections at Rosenborg Castle. Also in 1865, after the death of C.J. Thomsen, he became Director of the Royal Museum for Nordic Antiquities, and in 1866 Director of the Ethnographic Museum, while still being Inspector for the Conservation of Antiquarian Monuments. From 1874 to 1875, he was briefly Minister for Education and Ecclesiastical Affairs. Worsaae became a member of the Royal Danish Academy of Sciences and Letters in 1852, and he was in 1865 elected vice-president of the Royal Society of Northern Antiquaries.

Major Accomplishments

Worsaae developed early an interest in archaeology and began collecting antiquities as a schoolboy. As a young student he undertook archaeological excavations and published the results in *Antikvariske Annaler* 1838–1839 and 1840–1841. Still during his early career, he was engaged in disputes with established scholars, opposing their misinterpretations of archaeological finds as evidence of historical myths. Worsaae based his research on the work by C.J. Thomsen, who introduced the Three-Age System, dividing the time before the beginning of history in a Stone Age, a Bronze Age, and an Iron Age. He dissociated himself from the traditional antiquarian practice of collecting, emphasizing the importance to document archaeological finds in their context as well as recording the association of archaeological finds, thus introducing modern archaeological methods. In 1843 he published a survey of Danish prehistory according to the Three-Age System and with explanation of archaeological practice: *The Primeval Antiquities of Denmark*. It attracted international attention, when translated into German (1846) and English (1849). After a journey to England, Scotland, and Ireland in 1846–1847 (Jensen 2007), Worsaae in 1851 issued a book on the remains of the Danes and Norwegians in England, Scotland, and Ireland (English edition: Worsaae 1852). He continued the work by Thomsen and succeeded in subdividing the three main periods of Danish prehistory. In 1848 he was attached to the "Lejre Commission" together with the botanist J. Steenstrup and the geologist J.G. Forchammer with the purpose of investigating the shell-mounds along the ancient coastlines. The Danish word for shell-mound, *kjøkkenmødding*, has since become a loanword in many languages. Inspecting the shell-mound at Mejlgaard in Jutland in 1851, Worsaae found

simple stone artifacts different from those found in megalithic tombs. He concluded that they were older than the Neolithic and thus suggested a division of the Stone Age into an earlier and later period. Worsaae also divided the Bronze Age in an early period with inhumation and a late period with cremation burials, a division supported by stratigraphic observations during the excavations of grave mounds. His datings of the finds became known, when he published an illustrated catalogue of prehistoric artifacts in chronological order in 1854, with an updated edition in 1859 (English edition: Worsaae 1882). In 1865 he divided the Iron Age in three periods. The first one contained weapons found in bogs, like the finds from Torsbjerg in Schleswig, which he interpreted as weapon sacrifices. To the second period of the Iron Age, he referred the gold finds of the Migration Period and to the third objects from the Viking Age. He also interpreted male or female equipment from the Bronze Age such as weapons or ornaments found in bogs as votive depositions. The work by Worsaae was not only fundamental to Danish archaeology but had an impact on the development of archaeological method in general, especially in Scandinavia. Outside Scandinavia the Three-Age System became gradually accepted towards the end of the nineteenth century.

As Inspector for the Conservation of Antiquarian Monuments, Worsaae was assigned by the Danish King Frederik VII to conduct the excavations of the royal grave mounds at Jelling in 1861. His main accomplishment as responsible for the ancient monuments, however, was the implementation of a national survey. In 1873, on Worsaae's application, the Danish parliament gave an annual appropriation for a systematic inspection and documentation of prehistoric monuments in Denmark. It was carried on until 1932 by the National Museum, and the resulting register has formed the basis for later heritage administration as well as for research in ancient monuments in the country ever since.

Wreck Site Formation Processes

Colin J. M. Martin
University of St Andrews, St Andrews, Scotland, UK

Introduction

All terrestrial archaeological sites are, by definition, places where human agency has modified a natural environment by rearrangement (digging, building, removing, or bringing in material) and by the processes of life and death (food

production, processing, and consumption; waste disposal; making, using, and disposing of artifacts; acquiring goods from elsewhere; cultural and belief-related activities; and burial). These transforming inputs, which directly reflect human behavior and activity, are known as *cultural formation processes* or C-transforms. The environment is also constantly modified by *natural formation processes* or N-transforms. These may be cataclysmic and terminal, such as sudden burial in volcanic ash. More usually they are gradual and progressive and include the natural processes of decay and erosion, the deposition or removal of soil, the buildup of vegetation, fire, and the activities of burrowing animals.

Definition

These transforms induce changes whereby a once-functioning focus of organized human activity metamorphoses into the archaeological signatures encountered today. If the processes which brought about the changes are understood, it is possible, in theory at least, to work backwards from the observed remains and their associations to establish an understanding of the site when it was a functioning entity. Although this ideal is rarely achieved in totality, the study of a site's formation processes – how it reached the state it is in today – is the key to interpreting archaeological features of every kind (Schiffer 1987; Renfrew and Bahn 1991: 44–47).

Key Issues/Current Debates/Future Directions/Examples

Shipwrecks

Cataclysmic events which bury a site quickly, such as the entombment of Pompeii or the engulfment by sand drifts of the Neolithic village at Skara Brae in Orkney, are often the easiest formation processes to interpret, since they seal the archaeology in a tight context at a single moment, and limit subsequent re-ordering and decay. A shipwreck too is a cataclysmic deposition, but the factors which affect its formation as an archaeological site differ in several important respects from a site created by a terrestrial disaster.

In the first place a ship is a highly organized and completely mobile entity, so the location of its wreck is usually fortuitous. From the time its keel is laid, and especially from the start of its final

Wreck Site Formation Processes, Fig. 1 *Mary Rose* – a partially intact wreck (Colin Martin)

Wreck Site Formation Processes, Fig. 2 The *Dartmouth* (1690) – a continuous wreck site with discernible patterning (Colin Martin)

voyage, its ultimate fate is conditioned by C-transformation factors – how it was designed and built, how it was operated and managed, and particularly how attempts were made to avoid or mitigate the wrecking when the final disaster loomed. All these factors are the products of human input and behavior, but they are affected and modified by N-transforms, particularly the weather, currents, and the location of hazards such as lee shores or reefs.

A wrecking event can be characterized as the moment at which the organized entity represented by a vessel's structure, contents, and crew, together with its systems of propulsion, control, and management, begins an irreversible process of change in which it leaves the world of human artifice (the C-world) and reverts to nature (the N-world). This transformation is often extremely dynamic, as when a ship strikes a reef in heavy seas and disintegrates in seconds. But it may, as in the case of a hull that settles into a benign environment of soft sediments, be a gentle and gradual process. In both cases, however, the wreck will represent a massive environmental anomaly which is unstable, lacks integration with its surroundings, and is prone to further disintegration, decay, and dispersal by N-transforms. These may extract some material. Buoyant items, unless trapped, will simply float away, while other losses will accrue more slowly to abrasion, corrosion, and biological attack. Much of the surviving material will be redistributed by tides, surges, currents, and wave action that may result in the breakup of structures and the transport elsewhere of their fabric and contents. These effects are influenced by the topography, geology, and sediment regimes of the sea bed on which the wreck lies.

Once the dynamic phase of a wreck's integration with the sea bed is complete, a static or stabilized state will normally follow as the remains settle into a state of balance with their environment. This can happen quickly and perhaps with little change to the ship's original form, as when a vessel sinks into and is encapsulated in semifluid mud. On the other hand, the dynamic phase may be short-lived but so violent that much of the vessel's substance and most of its coherence is lost by the time stability is achieved. Such a formation will almost invariably be fragmentary, jumbled, and perhaps spread over a wide area. The situation may be further complicated if the wrecked ship, or parts of it, is transported by wind or current while breaking up. This can create a linear scatter of objects and sub-formations, each perhaps further dispersed by secondary

Wreck Site Formation Processes, Fig. 3 The *Kennemerland* (1664) – a discontinuous wreck with little discernible patterning. (Colin Martin, adapted from Muckelroy 1978: 173)

actions, spread along the axis of the wreck's trail of destruction.

The circumstances of a shipwreck and the attendant environmental inputs determine its eventual characteristics as an archaeological site formation. At one end of the scale, a vessel may survive almost intact, with its contents more or less complete and in situ, as, for example, the *Mary Rose*, which sank near Portsmouth, England, during an engagement with the French in 1545. At the other extreme a ship may be so broken up and dispersed, and its component parts so reduced by mechanical, chemical, and biological degradation, that it effectively ceases to exist (Figs. 1, 2, 3, and 4).

No two wreck formations are the same, since the complex and interacting variables that constitute the environmental setting, the nature of the ship, and the circumstances of its loss will combine to create a set of attributes unique to each site. Levels of archaeological survival can therefore range from almost intact to virtually extinct. Most wrecks, however, lie between these two extremes and may be categorized either as "continuous" (sufficiently coherent to allow a degree of reconstruction to be attempted) or "discontinuous" (too scrambled for meaningful conclusions to be drawn) (Muckelroy 1978: 182–214). But a fuller understanding of formation processes will reduce the size of the latter category, for there is an

Wreck Site Formation Processes, Fig. 4 Flow diagram of wreck site formation processes. (Colin Martin, adapted from Muckelroy 1978: 158)

ultimate logic to the dispersal patterns of every wreck.

Writing Archaeological Fiction

Mike Adamson
Flinders University of South Australia, Adelaide, SA, Australia

Introduction and Definition

The archaeologist has become a mainstay of popular fiction, indeed almost a cliché. The learned professor, aspiring student, hard-bitten field professional, and "bookish" laboratory technician have all become stereotypes, easily incorporated into a narrative whose ultimate goal, at least in film, is generally light entertainment. More serious treatments are typically literary, but both reflect the degree to which archaeology has assumed a role in the public consciousness as a glamor profession. For the diligent writer of archaeological fiction, the challenge is to bring integrity to a field easily trivialized.

Key Issues/Examples

No inventory of archaeological fiction could ever be complete, and such a survey is beyond the purview of this essay, but some examples deserve emphasis. The reader of classic fiction is well-served, and though the field has not been extensively explored, some seminal examples are readily accessible. Thomas (1976) surveyed high points in the British creative literature (1880s–mid-1970s) and asked how well the reader was really served by writers' understanding, attention to detail, or indeed respect for the field – generally not well. Similarly, Holtorf (2014) examined the public face of archaeology and the popular tropes to which the field has been welded – adventurer, detective, revealer, and caretaker.

Early writers cared little for the practical realities of the work, often a single individual would be cited as carrying out extensive excavation unassisted (Thomas 1976: 310), while the niceties of meticulous recording to place discoveries in usable context are also glossed over or ignored. Such an approach plays to the drama of the moment, in which the archaeology is background only, and this mechanism remains in force today: science is subservient to storytelling, obliging the writer to manage affairs skillfully if he or she is to both create marketable fiction and do the science justice.

Literature

In the twentieth century, archaeology blossomed in the public consciousness, both as an individual field and as the informative underpinning for creative endeavors such as the historical novel. That it has almost become its own genre can easily be judged by market research: at time of writing, the online book market Goodreads lists 79 titles under "Best Archaeology Thriller Books," and 133 as

"Popular Archaeological Fiction Books." Best-selling names like Dan Brown, Jack McDevitt, and Clive Cussler are high in the mix – though only the latter is recognized as having particularly relevant experience in the form of his creation of the real-life NUMA organization (based on his fictional equivalent, for the preservation of US maritime history through underwater archaeology) and his featuring of real scientific figures in fictional contexts. That archaeological fiction now carries the expectation of credibility may be seen in the review of fiction alongside technical and academic volumes by some journals (e.g., *Public Archaeology*).

To discuss just a few highly contrasting examples, one might consider Wilbur Smith's remarkable, experimental 1972 novel *The Sunbird*, actually two novels in one. The ancient land of Ophir is believed to have existed – as witnessed by its mention in ancient texts and exemplified by the 1946 Tel Qasile (Tel Aviv) pottery shard (e.g., Berlyn 2006; Kitchen 1989) on which is inscribed in Paleo-Hebrew script assigned to the eight century BC a receipt, to someone named Beth-Horon, for 30 shekels' worth of gold imported from Ophir. Its location remains unknown to science, though best guesses place it anywhere between southern Arabia and India. Smith placed it on the Atlantic coast of Africa, north of the Namib Desert (Phoenician fleets journeyed as far west as Spain and are thought to have explored the Atlantic margins of Iberia and Morocco (e.g., Harden 1948; Pearce 1980), so continuing southward for gold is not beyond reasonable artistic license). The first novel describes the archaeologists finding the lost kingdom and excavating evidence of what seemed to be the last stand of its people before its final destruction, while the second dramatized the ancient events based on the modern interpretation. The scientists discovered themselves the reincarnation of the ancient king and high priest too, always a good literary method of tying timeframes together. The visual metaphors of the cover of the 1984 Pan edition could not be more explicit; machine guns go so well with treasure and ancient ruins: it seems most popular archaeologists, especially on film, are usually heavily armed.

A second example might be *The First Americans* by Kathleen O'Neal Gear and W. Michael Gear, archaeologists of note, whose multivolume saga of the indigenous peoples of North America from the Stone Age to immediate pre-Columbian times are bestsellers. They have another series set among the Anasazi culture, combining the mystery genre. At time of writing, they have co-written 37 novels, with more on the way, including those individually authored. A sharp distinction may be made between such work and the traditional historical genre because history is defined as that which derives from documentary sources passed down from earlier times, while the first Americans northward from Mexico were largely (though not universally) nonliterate peoples whose antiquity has, to significant extent, become apparent through archaeology. In this sense, Romano-Celtic narratives *might* be regarded as near historical because Roman documentation is ever the starting point, but when putting flesh on the bones of nonliterate cultures, revealed in part or entirety through contemporary science, the definition of historical must, perforce, be shed. It becomes its own subgenre – the term "archaeo-historical" would seem appropriate.

Finally, straddling the line between historical and archaeo-historical, one might consider novels of Ancient Egypt, a popular genre in its own right, from Pauline Gedge's *Child of the Morning* and *The Oasis* to the works of Paul Doherty and Michael Asher. Elizabeth Peters' long-running *Amelia Peabody* series combines sleuthing with science in Agatha Christie's Egypt – a winning combination of genres. Christian Jacq's extensive writings, including the mutlimillion copy best-selling *Ramses* pentalogy, have captured public imagination, which is unfortunate in the sense that Jacq, despite being a Sorbonne-trained Egyptologist, chose to write romantic fiction rather than historical. That he knew the audience he was writing to is demonstrated by his success, however, it quickly becomes apparent that his Ancient Egypt is almost painfully "sanitized" for appeal to modern sensibilities.

A strong case can be made for archaeology being an invaluable tool for writers of "speculative fiction" – science fiction and fantasy. Thomas

(1976: 316) appreciated this. That the field informs fantasy – provides scenarios, fleshes out details, and generates and supports the great model of human descent from earlier ages so richly used by many fantasists – is undeniable. The "golden age" fantasists of the 1920s and 1930s – Robert E. Howard, H. P. Lovecraft, Clarke Ashton Smith, August Derlith, and others – developed worlds made at least metaphorically real by the discoveries taking place in Egypt, Mesopotamia, Mesoamerica, and elsewhere, filled with cyclopean ruins and unknown or legendary peoples given reality through the implicit notion that their scientific provenance had simply not yet occurred. In this sense, the products of archaeology, both artefactual and theoretical, underpin even the wildest speculations and excursions into the supernatural. Unfortunately, few writers are able to bring to bare the technical knowledge to flesh out their worlds with scientifically consistent and compelling detail. Though this is artistically unnecessary, real compulsion to the discerning reader may well lie in the details. Reiss (2015) points out: "Getting things wrong doesn't necessarily matter. But getting things *right*, even just one or two small things right, can convey an authenticity that will carry the weight of any number of wrong assumptions."

However profoundly archaeology informs fantasy, the science itself can be seen as a subgenre – of adventure or romantic fiction – while inviting the reader educationally into its own inner workings. Adrien Praetzellis has penned novels which neatly bridge the gap between fact and fiction; the 2003 *Death by Theory* and its 2011 sequel *Dug to Death* constitute useful beginners' guides to theory and method in the form of an engaging fictional narrative. Likewise, Sarah Milledge Nelson's novels of ancient Asia (e.g., *Spirit Bird Journey* and *Jade Dragon*, both published in 2009) are extrapolations of little-known epochs based on the evidence to hand. In the former, her protagonist visits the era in question in dream, allowing the reader to encounter as a living culture the society investigated scientifically in the balance of the text. Such works are distinct from the Gears' historico-archaeological approach and Jacq's romanticism by archaeology itself being a functional component of the narrative.

Film and Television

The popularity of archaeology as a storytelling medium in the last 40 years may with some confidence be laid at the feet of Hollywood. Paramount's 1981 release Raiders of the Lost Ark in one stroke defined and condemned a genre, for science was subserviated to adventure from the outset and the supernatural was thematically emphasized. The archaeologist as an archetype became a heavily armed man of action, the irony in this being that Indiana Jones is acknowledged as being based, not on any member of the archaeological profession but on the great American paleontologist Roy Chapman Andrews who led pioneering expeditions to Mongolia in the 1930s. "The man in the hat" has become a cliché of modern entertainment yet, contradictorily, remains the only figure of the genre to state explicitly what the field is or is not and to cite proper research procedure and theory (Kobialka 2017: 214). Gladstone (2014) defends Dr. Jones as being, far from a *bad archaeologist* by modern standards, a *good adventurer* by the traditional expectations of the era in which he was trained.

The Mummy films hung glamor and supernatural horror on a historico-archaeological context, something both the *Tomb Raider* games, films, and comics and the *Relic Hunter* TV series embody in modern times. To offer a polarized example, BBC's 20-season nonfiction *Time Team* did much to popularize the science, and while its appeal has been to the benefit of the field overall, many archaeologists wince at the haste and sometimes unavoidably destructive methods (e.g., mechanical excavation) employed.

Comics

The field of graphic narrative offers a unique balance between written and filmic media, and comics have exploited archaeological knowledge to depict a variety of narratives in historical and

fantasy contexts. Eric Shanower's *Age of Bronze* is a highly regarded example, telling the story of the Trojan War in a classic, un-sensationalized style of black and white line art. Frank Miller's *300* began life as a comic before being filmed, and here archaeological detail of fifth-century BC Greece was idealized into a fantasy context, though the depiction of Sparta and the daily life of the period was commendable. *Heros the Spartan* is the highly acclaimed comic strip penned by Tom Tully and illustrated by Frank Bellamy, for the British comic *Eagle* from 1962 onward, and remains remarkable for its graphic detail. In the UK, Pat Mills' *Slaine* has run nearly 40 years in the weekly *2000 AD* and, while telling Celtic adventures in high fantasy mode, is perhaps unique in the degree to which archaeological relics are depicted. Mr. Mills, whom this writer had the pleasure of interviewing in 1999, would often direct his artists concerning the antiquities he wished to appear, supplying them with pages from textbooks to guide the art.

The Writer's Approach

To write archaeologically one must perforce know the field. Journals and textbooks are the province of the specialist with adequate time. Fagan (2006) provides an entertaining framework for the aspiring writer of nonfiction to suit the voracious public appetite for engaging narratives, both about practical scientific work and the projected pasts based thereon. Praetzellis and Praetzellis (2015), however, approach the fictional sphere in their enacted narratives, seeking reconstructed humanistic meaning from raw data as a culmination of the interpretive phase. This process transposes information from fact to fiction to illuminate it for layman and specialist alike. This is as close to a formalized approach as one might find yet is likely too restrictive for most casual writers.

The writer who seeks to use archaeology as a background for drama must first ask for what market the work is intended. On the evidence of many financially successful book, film, or television series, if the goal is to tell an adventure, romance, or fantasy, then the quality of the archaeological detail is unlikely to be a factor in an editor's decision. Story, characterization, pacing, and engagement are the paramount qualities, and only when they have been satisfied will the nature of the scientific background apply.

On the other hand, if the marketplace is literary drama, more diligence may be required (though, it must be acknowledged, not necessarily). If the ambition is to produce a work of dignity and credibility, the quality of research then becomes a hallmark and selling point. As the traditional historical novel is expected to accurately reflect the current state of research into any given period, and the literary crime novel should properly relate police and legal procedure, the archaeological work may be expected to do appropriate justice to its field. Even so, all the rules of fiction apply, be they pacing, characterization, narrative/dialogue balance, expositional limitations, etc.; the technical background cannot swamp the characters and events which actually comprise stories.

Among the dos and don'ts are some obvious ones – don't rehash clichés, stereotypes, and classics; they come dangerously near to "fan fiction" and will not impress editors. As the number of would-be fantasy writers who to this day can only repackage Tolkien is legion, so would editors be disinclined to look favorably on adventure writers locked too firmly into the Indiana Jones or Lara Croft tropes and much less so the writer of literary fiction. Likewise, mapping the present day too literally onto the past in terms of familiar behaviors, attitudes, and imperatives, to facilitate reader comfort, is both a scientific sin and counter-educational in terms of the substance of any work.

The most important *do* any working archaeologist would cite can only be research accuracy. Presenting the reader with properly reported facts, reasonably interpreted, opens the field to drama on a solid basis of credibility, and this may be assigned to the practice of due diligence. In reference to the act of recreating past times as experiential entertainment, Holtorf (2017: 6) said: "The past does not have to be genuine in the sense that it once 'really' happened, but it needs to be credible as an authentic experience about a past that *could* have happened."

Reasonable speculation is also a prime ingredient of creativity. For instance, the supernatural may be a theme in any context, but the supernatural *as tangible reality* belongs in the adventure and fantasy fields, while academic analysis of past cultures' taboos, spirituality, and cultic practices, embracing the supernatural, is legitimate fodder for the most dignified of tracts. The difference is in the treatment – the pulp writer may have the long-dead spirit rise to object in person to its tomb being violated; the literary author derives drama from perhaps a black market trade in the antiquities in question.

Purpose and Meaning

From an epistemological standpoint, archaeology is complicated by its own nature – secondary observation and deduction, rather than primary observation. Doubt may always be encountered in the constructions placed upon the material remains of other times, and interpretive philosophies (epistemological idealism, positivism, and realism) have been constructed to make sense of data (Trigger 1998). Petersson and Holtorf (2017) cast the very practice of projecting our thoughts upon other times in a fresh light. Their model offers the possibility that every writer engages in a fundamental projection of potential alternate reality when they create fiction – that all stories have an independent existence which carries its own credibility and integrity. They posit that absolute historical accuracy – divorced from modern context and perceptions – is impossible and for the purpose of entertainment unnecessary: any story is a melange of elements which speak to the viewer and carry meaning in the viewer's present lived reality. In different words and context, Praetzellis and Praetzellis (2015: 125) acknowledge the same difficulties and possibilities.

If this is the case, a narrative expressing an internally consistent world view, and which is constructed with integrity, taking into account a range of factors (economic, social, spiritual, geographic, technological) may take on compelling realism and "live" in the mind of the reader. If this world serves not only to entertain and divert but to challenge the reader to think at greater depth or indeed about our conceptions of past times revealed by science, it may be deemed a success.

The public's fascination with archaeology seems perennial. It may be the identification with glamor (which many a field worker would roundly reject), the remote regions to which the profession takes its workers (though camp conditions are rarely up to tourist standard), or perhaps a fundamental fascination with being able to, literally, dig up anything from secrets to treasure. The fact that this is not what archaeology is actually about is beside the point – as Holtorf (2007, *cited in* Kobialka 2017: 213) pointed out, a recent survey found the best-known archaeologists in the world are Indiana Jones and Lara Croft. The potential frustration for professionals inherent in this cannot be underestimated; thus it is perhaps the duty of the writer of archaeological fiction to repay something of that debt – do the field justice, with respect, while preserving at least a hint of the wide-eyed delight with which students encounter the larger world of their dreams.

This is more or less Thomas's (1976: 318) position that the field is still waiting for the great archaeological novel, but it *may* have to write it itself. His closing remark offers a delicious irony; he said that unless archaeology brought forth a novelist capable of doing the field the justice it deserves *from within*, who knows what "travesties" would come from without. In the 40 plus years since this remark was penned, archaeologists have indeed accepted the challenge – the abovementioned Nelson, Praetzellis, and Gear and Gear among them – though whether any have fulfilled the dream quite as Thomas meant it remains open to debate. The irony, however, is that *Raiders of the Lost Ark* was released just 5 years after Thomas' comment. Hollywood may be depended upon to fill *any* void.

Wu, Rukang

Xinzhi Wu
Department of Palaeoanthropology, Institute of Vertebrate Palaeontology and Palaeoanthropology, Chinese Academy of Sciences, Beijing, China

Basic Biographical Information

Born in Wujin County, Changzhou Municipality, Jiangsu Province, eastern China, Rukang Wu (also known as Woo Ju-Kang before 1967) received a B.A. from the National Central University (then at Chongqing) in 1940. After graduation, he worked with Dingliang Wu (1894–1969) (also known as Woo Ting-Lian before 1967) in the section of Anthropology of the National Research Institute of History and Philology, Academia Sinica (then at Kunming, Yunnan Province), where they conducted studies on extant human skeleton and a number of field survey on different ethnic groups in Guizhou Province. In 1941, he published his first scientific article in a journal of Academia Sinica, the study of axes and the atlas of modern Chinese. Near the end of 1946, Rukang Wu left for the United States where he earned a doctoral degree under the supervision of Mildred Trotter at the Washington University Medical School in St. Louis, Missouri. He spent the summer of 1948 studying paleoanthropology under the direction of T. Dale Stewart at the National Museum of Natural History, Smithsonian

Institution, Washington, DC. In the autumn of 1949, Wu returned to China and began to work at the Dalian Medical College as the head of the Department of Anatomy. In 1956, he moved to the Laboratory of Vertebrate Paleontology (now the Institute of Vertebrate Paleontology and Paleoanthropology), Chinese Academy of Sciences, where he has made the first study of nearly all human fossils found in China between 1949 and 1966.

Major Accomplishments

During Rukang Wu's tenure at the Institute of Vertebrate Paleontology and Paleoanthropology, he studied human fossils of Middle Pleistocene origin, including Zhoukoudian, Maba, Chenjiawo, Gongwangling, Yunxian, Xichuan, Hexian, and Jinniushan, and of Late Pleistocene origin, including Ziyang, Dingcun, Salawusu, Liujiang, and Jianping.

Rukang Wu also studied *Gigantopithecus* from Daxing and Liucheng in detail, as well as *Dryopithecus* teeth from Kaiyuan. In the late 1970s, he organized a comprehensive study of the Zhoukoudian site. The result of this work provided a series of chronometric data for the different strata of the deposits in the cave and showed that *Homo erectus* had probably occupied the site for at least 200 kiloyear.

During the 1980s, he and colleagues excavated at Shihuiba, Lufeng, Yunnan Province, and found a lot of hominoid fossils. Initially, they divided the assemblage into two genera: *Sivapithecus and Ramapithecus*. In 1987, he proposed a new genus, *Lufengpithecus*, to represent all hominoid fossils from this site. This new genus is generally accepted by the international community.

During the 1960s, Rukang Wu proposed that the unique characters of true humans are not formed altogether in a short period. Instead, these characters appeared at different times in a long transition period from ancient apes toward humans. Erect bipedal walking and the ability of manufacturing tools marked the beginning and termination of this transition period, respectively. The enlarging of the brain and the development of language and consciousness and society were forming gradually during this transition period. He introduced the term "neoanthropology" to embrace all of the subfields studying the variation and changes of physical characteristics of modern humans as a whole.

In 1982, he founded the journal, Acta Anthropologica Sinica, which is the only journal dealing with paleoanthropology and physical anthropology in China. He is a member of the Chinese Academy of Sciences and was the honorary president of the Chinese Association of Anatomical Sciences.

Wylie, Alison

Patty Jo Watson
Department of Anthropology, Washington University, St. Louis, MO, USA

Basic Biographical Information

Alison Wylie (Fig. 1) is an internationally known feminist philosopher of science and a leader in the philosophy of archaeology. A Canadian by birth, Wylie became acquainted with field archaeology during early childhood. Both of her parents were long-time avocational archaeologists who worked

Wylie, Alison, Fig. 1 Alison Wylie

as volunteers for projects in England as well as in Canada.

Wylie received a B.A. Honours (with Distinction in Philosophy and Sociology) from Mount Allison College in 1976. As an undergraduate, she gained fieldwork experience at Fort Walsh, a nineteenth-century Northwest Mounted Police post, and the Fortress of Louisbourg. She also took a history and philosophy of science course where she encountered the work of Merrilee Salmon and used it in a term paper on the possibility of a Kuhnian revolution in contemporary archaeology. In the fall of 1976, Wylie enrolled in the graduate program in the History and Philosophy of the Social and Behavioral Sciences at the State University of New York at Binghamton. She met and worked with several young archaeologists in the Department of Anthropology, notably Charles Redman, Margaret Conkey, and John Fritz, who were enthusiastic advocates of the New (or Processualist) Archaeology. She spent the summer of 1977 at Grasshopper, the University of Arizona's field school. Wylie completed her M.A. in Anthropology (1979) and a Ph.D. in Philosophy (1982). Her dissertation, focusing on positivism and the New Archaeology, was written under the direction of the realist philosopher Rom Haré and advised by Redman.

Wylie was hired as an Assistant Professor at the University of Western Ontario in 1985, where she was promoted to Associate Professor (1989–1993) and then Professor (1993–1998). In 1998, she moved to Washington University at St. Louis to take the position in Philosophy and the Program for Social Thought and Analysis. In 2003, she joined the faculties of the Department of Women's Studies at Columbia University and the Department of Philosophy at Barnard College. She is curre ntly Professor of Philosophy at the University of Washington in Seattle (2005–). She is the founder and coordinator of the Science Studies Network at the University of Washington and director of Biological Futures in a Globalized World, a project designed to foster the development of an integrated research ethics curriculum. She has held numerous visiting appointments including those at the Center for Advanced Study in the Behavioral Sciences (1995–1996) and the Clayman Institute for Gender Research (2005–2006) at Stanford; the University of Denver (1995); the University of California, Berkeley (1990–1992), Columbia University, and New York University (2001–2002); the École des hautes études en sciences sociales in Paris (2003), Reading University (2010), and Durham University (2012–2013).

Major Accomplishments

Wylie's primary research focus in archaeology is on archaeological inference; that is, how archaeologists derive interpretations of past times and places from limited knowledge of an intrinsically highly incomplete body of evidence – the archaeological record – and how they support their claims to knowledge of those times and places. One of Wylie's earliest contributions was her essay in Ian Hodder's book *Symbolic and Structural Archaeology* (Wylie 1982a), which provided epistemological support for structural archaeology. She showed that the most promising of the new structural perspectives exploited methodological approaches that were scientific and testable.

Wylie has made major contributions to the application of analogical reasoning in archaeology. She intervened in the debate between Patty Jo Watson and Richard Gould concluding that Gould's arguments against analogy were

themselves analogical (Wylie 1982b). She reviewed the arguments against analogy offered by some New Archaeologists concluding that analogy is not categorically flawed, but it can be misused (Wylie 1985, 1988). The key is to work on both the source side and subject side of the analogy in order to secure it more strongly. She has also proposed an influential model of interpretation that involves a dialectical tacking between experience-near concepts and experience-distant concepts (Wylie 1989). This latter model was inspired by Clifford Geertz and his interpretive anthropology.

Wylie was an early exponent of the archaeology of gender. She participated in the famous conference organized by Joan Gero and Margaret Conkey at the University of South Carolina's Wedge Plantation. Her contribution was to review the delay of an archaeology of gender (given its significance in the other social sciences) and evaluate its prospects for the future (Wylie 1991). She concluded that archaeology can benefit from the established traditions of gender research and that gender studies can benefit from archaeology because only archaeology can begin to answer questions about long-term evolution and diversity of the sex/gender system. She followed this with a series of influential publications arguing that feminist approaches, among other critical perspectives, may well enhance the conceptual integrity and empirical adequacy of archaeological knowledge claims (e.g., Wylie 1992).

Wylie has also interrogated the idea of objectivity in science and its implications for both feminism and feminist archaeology. She argues that the thesis that theories are culturally constructed does not necessarily entail epistemic relativism, where anything goes. Rather, she advocates a perspective she calls "mitigated objectivity." In this case, multiple lines of evidence drawn from the natural and social sciences are mutually constrained when they converge, or alternatively fail to converge, upon a particular interpretive account (Wylie 2000). This perspective is broadly consistent with standpoint theory in feminist science. Knowledge is understood to be situated with respect to particular experiences and social values. Wylie (2003: 40) explains that the question of what standpoints make a difference cannot be settled in the abstract, but instead requires an investigation of problem-specific practices of knowledge production.

She is equally concerned with the sociopolitical contexts of archaeology as a discipline and of individual archaeologists working in diverse economic, political, and social settings internationally. She is frequently consulted on ethical issues in contemporary archaeology (Lynott and Wylie 2000; Wylie 2003). Her recent book, *Thinking from Things* (Wylie 2002), is a set of essays describing and discussing her philosophical engagement with archaeological theory and practice from the 1970s to the 2000s, a period of great change for global archaeology. Hence, it is a significant contribution to the intellectual history of archaeology in the late twentieth century.

During the past 30 years, several philosophers of science have displayed passing interest in archaeology, but Alison Wylie is the only one with substantial experience not only in field archaeology but also in writing archaeological reports. She is familiar with documentation of archaeological finds during excavation and with the inferential processes employed by archaeologists as they describe, analyze, and interpret their finds. She is widely known because of her publications in archaeological journals and her vigorous participation in professional gatherings of archaeologists. Her publications provide well-informed analyses of archaeological procedures in the field, in the lab, and in the ensuing reports by a long-term participant observer who is a professional philosopher of science. She is often asked to serve as consultant to archaeological projects and to help form policy for archaeological groups in various parts of the world. For all these reasons, Wylie occupies a well-deserved position as intellectual guide and counselor to the global archaeological community.

X

Xia Nai

KO Jada
Department of Anthropology, Harvard University, Cambridge, MA, USA

Basic Biographical Information

Xia Nai (1910–1985) was a major pioneer of post-1949 modern Chinese archaeology. Born in Wenzhou, Southern Zhejiang province, Xia became an archaeologist only after he received his Bachelor's degree in modern economic history from Tsinghua University in 1934. Upon graduation, he received the Boxer Indemnity Scholarship to study archaeology abroad. One of the requirements for the scholarship recipient was field experience. Accordingly, Li Ji, the director of archaeology department of Academia Sinica, and Fu Sinian, the director of Academia Sinica, provided an opportunity for Xia to excavate at the late Shang Dynasty (1350–1046 B.C.E) site of Xibeigang Royal Cemetery in Anyang city, Henan province. After his first archaeological field experience in 1935, Xia began his academic career in archaeology at the University College London (UCL). He initially studied classical archaeology with Perceval Yetts and later continued to pursue his PhD in Egyptology with Stephen Glanville, who was then the chair of Egyptian Archaeology and Philology at UCL.

The outbreak of the Second World War did not end Xia's academic pursuit offshore. Instead, Xia obtained the Douglas Murray Scholarship to conduct fieldwork in Egypt in 1939 at the Cairo Museum. In 1941, Xia returned to China and obtained a position at the Preparatory Office at the Central Museum (now Nanjing Museum). In 1943, he joined the Department of Archaeology of the Institute of History and Philology, Academia Sinica, first as an Associate Research Fellow, then as a Research Fellow, and finally was promoted as Acting Director in 1947. By the end of the Chinese Civil War in 1948, Academia Sinica was to be relocated to Taiwan. While Li Ji and Fu Sinian moved to Taiwan, Xia Nai remained in China and taught at Zhejiang University for a year. Since the departure of his major predecessors, Xia held the key to the success of the development of the field of Chinese archaeology in New China. In 1950, Xia was appointed Second Deputy Director of the newly established Institute of Archaeology. He then became the Director of the Institute between 1962 and 1982 and was elected President of the new Archaeological Society of China in 1979. Through his influence until his passing, he has left his avant-garde and scrupulous philosophy in almost every domain in the first chapter of post-1949 Chinese archaeology.

Major Accomplishments

While often acclaimed for his contributions to modern Chinese archaeology, Xia Nai is seldom recognized as the first Egyptologist in China. At UCL, Xia examined Flinders Petrie's Egyptian beads collection for his dissertation. His dissertation, *Ancient Egyptian Beads* (2014), was completed in 1943 but was not published until 2014. His painstaking effort in cataloging and analyzing of the beads was also reflected in the 1760 index cards he meticulously inked with descriptions, analyses, and drawings. The cards are now digitized in the UCL museum online catalogue (Fig. 1). As a graduate student, Xia also participated in several international excavations. He excavated at Maiden Castle in Britain, Armant in Egypt, and Tell el-Duweir in Palestine. Guided by his mentors, Xia was equipped with solid analytical and field techniques and was inspired to develop his life-long academic interest in the historical connections between the East and the West as reflected in his subsequent research. An example of such is his first collection of essays published in Xia (1961), which covers topics related to ancient China and its economic and cultural relationships with Rome and Persia through the study of silk, silver, and currencies.

In his postgraduate career back in China, Xia led multiple field projects and made discoveries that revolutionized the field. For example, he discovered features related to the Shang culture at Huixian in Henan province, providing the first archaeological evidence of Shang influence outside of Anyang. In a survey conducted in Hunan province, he accurately identified Mawangdui as a Western Han site (206 B.C.–A.D. 9), which led to the subsequent excavation of the site thus the

Xia Nai, Fig. 1 Card 66 – 1 of the 1760 index cards Xia Nai recorded of Flinders Petrie's Egyptian beads collection. (Taken from The Xia Nai Index of Egyptian Beads in The Petrie Museum of Egyptian Archaeology 2014. Courtesy of the Petrie Museum of Egyptian Archaeology, UCL)

Xia Nai, Fig. 2 The two Gansu Yangshao (Majiayao) style painted pottery sherds excavated from Tomb No. 2 at Yangwawan, Gansu province. (Taken from Xia 1948: Fig. 5)

understanding of the Han burial systems. Of all the projects Xia headed, he is most famous for the 1945 excavation at the site of Yangwawan in Gansu province. While excavating Tomb No. 2 of the Qijia culture (ca. 2200–1600 B.C.), Xia discovered two Gansu Yangshao culture (ca. 3300–2000 B.C.) (later on renamed by him as Majiayao culture) painted pottery sherds (Fig. 2) from the fill of the tomb. In his article "New Discovery of a Ch'i Chia (Qijia) Culture Cemetery" (1948), Xia discusses the taphonomy of the site and concludes that the Yangshao sherds were discarded prior to the burial of the Qijia deceased. The stratigraphic evidence rectifies Swedish geologist-turned-archaeologist J.G. Andersson's initial proposal that Qijia predated Yangshao. The subsequent projects in the Northwest that Xia headed provided additional evidence to revise the chronological system of prehistoric cultures in China. His work was also the basis for overturning the hypothesis that the early Chinese civilization originated in the west and entered China through the Silk Road into Gansu and then spread into the Central Plains. In every excavation that Xia headed, he employed the systematic scientific field methods adopted from one of his mentors Mortimer Wheeler, most famous for his excavation at Mohenjo-daro in Pakistan and his advanced systematic field excavation methods. These methods later on became the basis for the field excavation methods in China.

Xia's training and experience contributed to his strong advocacy of Marxist materialism and archaeological science. Xia's (1959) article, "Regarding the Naming of Archaeological Cultures," stresses the importance of anthropological and sociological considerations to the designation and study of archaeological cultures. Yet, Xia recognized the limitations of traditional archaeology in accurately reconstructing the cultural development of such cultures. Consequently, throughout his career, he encouraged interdisciplinary collaboration, particularly with natural sciences, taking a great leap forward toward the development of archaeological science. For example, after the development of the radiocarbon dating method by Willard Libby in the late 1940s, Xia immediately encouraged and supported the installation of a radiocarbon laboratory in China. When the lab was set up in the early 1960s, Xia provided a comprehensive chronology of the prehistoric cultures in China based on the absolute dates obtained from the lab in his 1977 article "Carbon14 Dating and Prehistoric Archaeology in China" (Fig. 3). Moreover, Xia collaborated with multiple metal physicists and utilized different analytical methods to understand metallurgical development in ancient China at Gaocheng in Hebei province that dated to the Shang Dynasty.

Apart from his own academic achievements, Xia also dedicated his postgraduate career to the

Xia Nai, Fig. 3 The chronological sequence of prehistoric cultures in China based on the absolute C14 dates produced by the first radiocarbon laboratory in China at the Archaeological Institute of the Chinese Academy of Social Sciences. The chart is divided into seven regions including the Central Plains region, the Upper Yellow River Valley (Gansu-Qinghai region), the Lower Yellow River Valley, the Middle Yangtze River Valley, the Fujian and Guangdong coastal region, the Southwest region, and the Northeast region. (Taken from Xia 1977: Fig. 1)

nurturing of a young generation of archaeologists and to promote Chinese archaeology to a wider audience. The collaborative effort of Xia and his colleagues such as Su Bingqi and Pei Wenzhong resulted in the unprecedented founding of archaeology as a specialized field under the History Department at Peking University in 1952. Moreover, beginning 1956, four short-term archaeological training programs took place under the leadership of Xia, during which he and the leading archaeologists at that time instructed survey and excavation methods to the participants. While Xia continued to actively contribute at the academic level, he also composed popular narratives such as *The Memoirs of a Traveler in Dunhuang* (2002). On the other hand, he took on editorial work for major journals including *Acta Archaeologica Sinica* and *Archaeology*. In 1985, Xia was appointed as the Editor-in-Chief of *The Encyclopedia of China – Archaeology Volume* and passed away in the same year in Beijing after suffering from a stroke.

Xiaochangliang: Geography and Culture

Liu Yang
Laboratory of Human Evolution, Institute of Vertebrate Paleontology and Paleoanthropology, Chinese Academy of Sciences, Beijing, China
University of Chinese Academy of Sciences, Beijing, China

Introduction

The Nihewan Basin, located in the valley formed by Sanggan River and its tributary, the Huliu River, which covers an area of about 9,000 km^2 with an average elevation of 1,000 m, in northwest Hebei province and northern Shanxi province, 50 km west of Beijing, is a key region for studying Chinese or even global Quaternary geology, paleontology, and Paleolithic archaeology. Research in the Nihewan Basin can be traced back to the 1920s, when French scholars E. Licent and P. Teilhard de Chardin and others found and studied mammalian fossils contained in Late Cenozoic fluvio-lacustrine strata near Nihewan village, which eventually corresponded to the Villafranchian fauna in Europe (Barbour et al. 1927). The lacustrine sediments in the ancient Nihewan lake basin were called the "Nihewan Formation" (Barbour 1924). In 1960s (Gai and Wei 1974) and 1970s (Jia and Wei 1976), the Hutouliang and Xujiayao sites were discovered. Paleolithic archaeology then became an important part of research here. In 1978, with the discovery of Xiaochanglaing (You et al. 1979), scholars began to study the Lower Paleolithic. This was the first time that Lower Paleolithic archaeology was studied systematically in the area, although the age of Xiaochangliang was

Xiaochangliang: Geography and Culture, Fig. 1 A map showing the position of the Xiaochangliang site. (After Ao et al. 2010)

controversial at that time. At present the Lower Paleolithic sites in the Nihewan Basin are known as one of the richest areas in North China, or even all of China. Over 20 Lower Paleolithic sites have been discovered, including 14 Early Pleistocene ones. They are located in the eastern part of the Nihewan Basin, around the Donggutuo Village and Cengjiawan Platform (Fig. 1).

Definition

The Xiaochangliang site (40°13′10″N, 114°3′944″E, altitude 916.52 m), whose name has been carved on the first bronze broad at China Millennium Monument's historical corridor in Beijing, is one of the most extensively excavated and prolific sites yet studied in the Nihewan Basin. It is located on the edge of Cenjiawan platform of the Nihewan cliff, Yangyuan, Hebei province. It was found by You Yuzhu, Tang Yingjun, and Li Yi, members of the Institute of Vertebrate Paleontology and Paleoanthropology (IVPP) in 1978. By now the site has been excavated several times, and the area has been excavated about 200 m^2.

The Xiaochangliang strata, belonging to the Nihewan Formation, are normal faults located at the boot wall of a Brown fault. The section of the strata is as follows:

1. Light-brown, silty, loosen loess. Thickness (Th.) 12.07 m
2. Light-red, loess with calcium tuberculosis, gradual transition from the underlying strata. Th.1.83 m

3. Gray-green, clayey silt with calcium TB. Th. 0.70 m
4. Brown-yellow, slightly viscous, silty sand, with calcium tuberculosis, gradual transition from the underlying strata. Th.1.16 m
5. Gray, viscous, clayey silt. Th. 0.92 m
6. Gray, calcareous cement layer and with 8-cm-thick gray silt. Th. 0.21 m
7. Gray, silt and clay. Th. 0.59 m
8. Brown-yellow silt, with thin bedding. Th. 0.95 m
9. Light-red, clayey silt. Th. 1.14 m
10. Brown-yellow, silty sand. Th. 1.38 m
11. Gray-green, sandy silt. Th. 1.01 m
12. Sallow, silty sand. Th. 0.49 m
13. Sienna brown, clayey silt, with calcium TB. Th.1.84 m
14. Brown-yellow, fine sand. Th. 0.18 m
15. Brown-red, clayey silt. Th. 0.21 m
16. Brown-yellow, silt. Th. 0.40 m
17. Brown-red, clayey silt. Th. 0.68 m
18. Yellow-green, clayey silt. Th. 0.49 m
19. Brown-red, silt, the bottom 30-cm-thick gravel layer. Th. 2.47 m
20. Gray, silty sand, with small gravel and fine gravel. Th. 2.42 m
21. Maliang (site name, about 0.78 Ma) layer, brown-yellow, fine sand, the lower part of the gray-green or light-gray silt layer of calcium TB. Th. 0.78 m
22. (22)TBS layer, thick layer of brown sand. Th. 19.13 m
23. Yellow-green, sandy silt. Th. 2.03 m
24. Light-red, clayey silt. Th. 2.80 m
25. Gray, clayey silt. Th. 0.50 m
26. Light-red, sandy silt. Th. 0.40 m
27. Yellow-green, silty sand. Th. 0.45 m
28. Brown-yellow, silty sand, below the bottom of a small gravel. Th. 0.19 m
29. Brown-yellow, sandy silt, the upper with a yellow-green clip gravel. Th. 0.66 m
30. Light-red, sandy silt. Th. 0.92 m
31. Gray-green, clayey silt, similar to Donggutuo (site name, about 1.1 Ma) layer A. Th. 0.13 m
32. Light-red, sandy silt. Th. 2.05 m
33. Gray-green, clayey silt, with bedding. Th. 2.20 m
34. Light-red, silty sand. Th. 0.38 m
35. Gray-green, silty sand. Th. 0.33 m
36. Brown-yellow, medium and fine sand. Th. 0.22 m
37. Light-red, sandy silt. Th. 1.32 m
38. Brown-yellow, Shanshenmiaozui (site name, about 1.33 Ma) layer, fine sand. Th. 0.09 m
39. Brown-yellow, sandy silt. Th. 0.99 m
40. Gray-green, silty clay, with horizontal bedding. Th. 1.29–1.86 m
41. Xiaochangliang layer: fine gray sandy silt. Th. 0.80 m
42. Light-red, clayey silt. Th. 0.21 m
43. Gray, silty clay, viscous. Th. 0.58 m
44. Brown-yellow, silty sand, with small gravel. Th. 1.37 m
45. Brick-red, silty sand. Th. 11.15 m
46. Gravel layer especially boulders. Th. 0.31 m
47. Purple, volcanic breccias, bared more than 10 m

The archaeological layer of Xiaochangliang site lies approximately 70 m below the Late Pleistocene Malan loess (e.g., You et al. 1978). Vertebrate fossils and artifacts were found associated within a fine gray sandy silt layer reaching 0.80-m thickness (You et al. 1978). A small investigation in 1990 found no discernible pattern of orientation of either artifacts or fossils, and the majority of artifacts appeared in fresh condition. That means it is an *in situ* buried site.

From the perspective of the 1816 stone artifacts assemblage (Fig. 2), the overwhelming majority of the artifact assemblage consists of flakes and flake fragments, along with some cores and clearly identifiable tools (You et al. 1980; You 1983; Chen et al. 1999). There are 96 cores, 342 flakes, 35 tools, and 1,343 blocks or debris. The stone artifacts are made predominantly of volcanic breccias, including cherts, chalcedonies, and agates, and cherts are the main raw material. An abundant source of raw materials can be found from the exposed bedrock, Jurassic volcanics, sediments, and Precambrian quartzite with cherty streaks which extremely fissured, at the vicinity of the Xiaochangliang site. Hard-hammer direct percussion is the main technology used to produce flakes. Most of the tools are semifinished products, and only few are refined products including

Xiaochangliang: Geography and Culture, Fig. 2 The stone artifacts from Xiaochangliang

various scrapers, points, borers, small chopping tools, and burins.

Except for the lithic products, there are also many mammal fossils, including *Allophaiomys cf. A. Pliocaenicus*, *Martes* sp., *Hyaena licenti*, *Palaeoloxodon* sp., *Hipparion sinense*, *Equus sanmeniensis*, *Coelodonta antiquitatis*, *Cervus* sp., *Gazella* sp., and *Bovids*.

The age of Xiaochangliang site, according to Zhu Rixiang and other studies, is 1.36 Ma (Zhu et al. 2001).

Key Issues/Current Debates/Future Directions/Examples

The hot topics in research at the Xiaochangliang site are as follows.

First is the culture development: primitive or progressive. Some researchers consider that it is characterized by random flake knapping, lacking tool retouch, and instability of shape (Chen et al. 2002), meaning that the lithic technology is original (Schick et al. 1991), but for other researchers (Huang 1985), it has many advanced traits, for example, some smaller blades and flake fragment with faceted platform were observed, and the types of stone tools are diverse, including various scrapers, points, borers, small chopping tools, and burins.

Second is the age. Since its discovery in 1978, given its importance, the Xiaochangliang site has attracted the attention of geologists and chronologists. However, its age had long been debated because of the unavailability of an accurate chronostratigraphic framework. Age determinations by electron spin resonance, thermoluminescence, and radiometric isotopic methods could not be satisfactorily applied to these artifact-containing strata because of the absence of required materials. Paleomagnetic dating indicates that the site lies below the Jaramillo subchron (Schick and Dong 1993), placing them at or shortly before 1 Ma, while Zhu et al. (2001) report an age 1.36 Ma (between the Oldovai and Jaramillo events) for the artifact-bearing lacustrine deposits at Xiaochangliang. However, by stratigraphic correlation (Wei et al. 2011), the age of Xiaochangliang site is considered to be over 1.50 Ma.

Third is the paleoenvironment. At present, the climatic context of Xiaochangliang site is unclear, and it is not yet known whether the occupation occurred during an interglacial or glacial period. The faunal remains include *Cervus* and *Gazella*, which do not imply cold conditions. Given the

evidence from Gongwangling as well as Central Asia (Wang et al. 1997), the occupation at Xiaochangliang 1.36 Ma ago was probably during a warm episode.

X-Ray Diffraction (XRD): Applications in Archaeology

Ervan Garrison
Department of Geology, The University of Georgia, Athens, GA, USA

Introduction and Definition

X-ray diffraction (XRD) is an analytical technique in which a prepared sample is bombarded with an X-ray beam at varying angles. The diffractometer measures the size of the "unit cell" – space between adjacent crystal planes – by virtue of the "d-spacing" (Fig. 1). Most archaeological samples are typically soil or sediments such as clays. Stoney materials can be analyzed and the only requirement of a material for XRD analysis is that it be crystalline. In the case of soil or sediments, the sample to be analyzed is in powder form. This allows the sample to present all of the possible crystal orientations in the minerals comprising the sample.

Key Issues/Current Debates/Future Directions/Examples

To prepare a sample, the material must be ground into a uniform consistency. This step randomizes the minerals in the sample. Samples are generally

X-Ray Diffraction (XRD): Applications in Archaeology, Fig. 1 Schematic of X-ray diffraction. The diffractometer measures the "d-spacing" between the crystal planes following Bragg's Law ($n \cdot \lambda = 2 \cdot d \cdot \sin(\theta)$), where n is the integer representing the peak of interest, d is the lattice spacing of the specific crystallized mineral or element, θ is the angle between the scattered X-ray and the incident radiation, and λ is the wavelength of the incident light

placed into an oven at a low temperature for 15–20 min to dry them out. The dry samples are then pounded with a mortar and pestle to a uniform powder. The powder is then pressed into a tablet using an aluminum disc frame, onto which 200 psi (pounds per square inch) is applied for 1 min. Pressing the powder prevents the incident X-rays from penetrating the sample too deeply, thereby creating some problems with the analysis, such as absorption, refraction, and reradiation of X-rays.

Then, samples are placed, one at a time, in the XRD diffractometer, and data are collected from 2 to 50 2θ at a step increment of 0.01° and scan speed of 0.1 s per stop. XRD data can be collected and saved using DIFFRACplus XRD Commander software by Bruker AXS, although other software is available.

Prior to interpretation, the raw diffractograms from the XRD machine have to be processed. Using the DIFFRAC*plus* EVA software by Bruker AXS, the Kα2 peaks and background noise are stripped, and the threshold sensitivity is adjusted

X-Ray Diffraction (XRD): Applications in Archaeology, Fig. 3 2-Theta, d-spacing, percent intensity peak data from XRD diffractograms and mineral interpretations for fine and coarse fractions of the alleged paleosol and horizon 3. Data are listed from greatest to least percent intensity and mineral interpretations are identified only for major components (>50% intensity in the fine fraction and >10% intensity in the coarse fraction)

X-Ray Diffraction (XRD): Applications in Archaeology, Fig. 4 Diffractogram of the coarse, bulk, and fine fractions of a suspected paleosol sediment. The larger peak is that of the quartz soil fraction. The second peak located at 24° is identified as feldspar

prior to performing a peak search to identify the major peaks in the diffractogram. Any significant peaks missed by the automated peak search are manually selected and added to the diffractogram record. Finally, potential mineral matches for each peak are identified using the general search option within the EVA software. Suspected minerals not included by the automated search are checked by conducting manual EVA searches for individual minerals. Peak intensity, 2θ, and d-spacing are used to identify the most likely mineral(s) responsible for each peak. The 2θ and d-spacing of suspected mineral matches are then compared to known index values and thereby verified or disqualified as a match using a Powder Diffraction Database Search software by Scintag, Inc.

An Example of XRD Identification of Paleosols

In the diffractograms shown below, one sees the mineralogic makeup of a puted paleosol collected within a soil profile exposed in a test pit located in the Georgia Piedmont near Athens, Georgia. The pit was located on a natural levee of the Middle Oconee River; thus, the parent material for the soils exposed in the walls of the pit is alluvial. One horizon is alleged to be a paleosol and is referred to hereafter as the "paleosol." The depth from which this horizon was originally sampled was not noted. The other horizon, referred to hereafter as "Horizon 3," was sampled from a depth of 134 cm. Figure 2 shows the soil profile in the field.

As expected, quartz created the most intense peak for the bulk and coarse fraction from both horizons. Figure 3 shows the tabulated XRD data shown graphically in the following diffractograms (Fig. 4). Potassium feldspar created the second most intense peak in the bulk and coarse fraction diffractograms for both horizons. Greater variability in terms of peak intensity was evident in the

X-Ray Diffraction (XRD): Applications in Archaeology, Fig. 5 Diffractogram of the paleosol bulk fraction and Horizon 3 sediment

fine fraction diffractograms for the two horizons (Fig. 5), although both possessed the same major minerals. Kaolinite, hydroxy-interlayered vermiculite (HIV), biotite, and muscovite created the largest peaks in both horizons. However, kaolinite created the most intense peak in the alleged paleosol fine fraction, whereas HIV was responsible for the most intense peak in the Horizon 3 fine fraction. Ultimately, XRD analysis successfully pinpointed differences between the fine fractions of the two horizons and confirmed their identities as Inceptisols.

X-Ray Fluorescence (XRF): Applications in Archaeology

M. Steven Shackley
Geoarchaeological XRF Laboratory, Department of Anthropology, University of California, Berkeley, CA, USA

Introduction

Edward Hall's abstract for his 1960 paper entitled "X-ray fluorescent analysis applied to archaeology" in the journal *Archaeometry* is just as appropriate one-half century later. X-ray fluorescence spectrometry (XRF) may be more "well

established" and is still "not suitable for some projects" even though they might seem so, and archaeologists might very much want XRF to be so. This chapter is dedicated to a brief discussion of the applicability of XRF analysis in archaeology.

How does XRF work, and more importantly when and where is it appropriate? There are a number of recent published works on the subject that delve into the subject in great depth and are highly recommended for further edification (i.e., Beckhoff et al. 2006; Potts and West 2008; Shackley 2011a; and the important Jenkins 1999).

Today the market is being flooded with, it seems, hundreds of portable x-ray fluorescent instruments (pXRF), but do they really do all that the marketing suggests (see Shackley 2011b; Speakman et al. 2011)? The recent edited volume by Potts and West (2008) is devoted to the portable instrument for a variety of applications in science and engineering, including archaeological stone and museum works of art, and more recently Ioannis Liritzis and Nikolaos Zacharias provide a critical evaluation of pXRF in obsidian studies as well as other archaeological materials (Liritzis and Zacharias 2011). Is there a need anymore for the desktop laboratory EDXRF? Can we as archaeologists get away with only a much less expensive pXRF? As an academic in a major university, I saw the upcoming students increasing interest in pXRF as a solution to a problem – is it a solution looking for a problem or a very real need to be able to carry great analytical power into remote field conditions? It may, indeed, be too soon to definitively answer these questions, but very recent newer versions of pXRF instruments and software may be resolving some of these issues.

The vast majority of archaeological XRF worldwide is applied to inorganic materials, mainly volcanic rocks, and there are very good technical reasons (for that see Davis et al. 2011; Lundblad et al., 2008). This does not mean, of course, that there aren't perfectly good reasons for analyzing ceramics or organics (Speakman et al. 2011). While pottery is "not a rock," it is composed of rocks and clay sediments that lend themselves to XRF analysis (Hall 2001; Neff 1992; Pollard 1996). The very real difference is that unlike volcanic rocks as an example, ceramics are not formed at very high temperatures in the mantle or crust and are not necessarily a reflection of human production.

What is very different from Edward Hall's XRF world is that archaeology as a discipline has changed markedly both theoretically and methodologically, due in large part to the tools and technology that are offered in the twenty-first century. Issues of social identity, equality, gender, national character, and native rights are all current and important issues in archaeology today and are being addressed with these new tools – XRF certainly among them (see Joyce 2011; Mills et al. 2013; Pollard and Bray 2007; Sillar and Tite 2000). Scholars have argued elsewhere that without our twenty-first-century archaeological tools, a twenty-first-century archaeology would be not much more than the New Archaeology of the 1960s or Culture Historical in nature (Shackley 2005; see also Joyce 2011). X-ray fluorescence spectrometry will play an important role as a "well established method" for illuminating our ever-changing problems in archaeology well into this century. What XRF will look like in another 50 years is impossible to imagine. The portables are probably a peep into that future.

History of XRF in Archaeology

X-rays were first discovered by the German physicist Wilhelm K. Röntgen (1845–1923) for which he won the Nobel Prize in 1901 (Röntgen 1898). Charles G. Barkla in 1909 found a connection between x-rays radiating from a sample and the atomic weight of the sample. In 1913, Henry G. J. Moseley helped number the elements with the use of x-rays, by observing that the K line transitions in an x-ray spectrum moved the same amount each time the atomic number increased by one, a primary theoretical precept in XRF physics (Moseley 1913/14; see Fig. 1 here). He is credited with revising the periodic tables which were based

X-Ray Fluorescence (XRF): Applications in Archaeology, Fig. 1 Schematic view of orbital transitions due to x-ray fluorescence (from Shackley 2011b: Fig. 2-1)

on increasing atomic weight, to periodic tables based on atomic number. He later laid the foundation for identifying elements in x-ray spectroscopy by establishing a relationship between frequency (energy) and the atomic number, a basis of x-ray spectrometry. The potential of the technique was quickly realized, with half of the Nobel Prizes in physics awarded to developments in x-rays from 1914 to 1924.

A Brief Discussion of the Principles of XRF

In EDXRF analysis, samples are irradiated with photons, usually from an x-ray tube or radioisotopic source. The primary x-ray beam excites electrons in the sample, causing it to emit secondary x-rays, i.e., to *fluoresce*. The emitted x-rays occur at energies specific to elements in the sample, appearing as peaks over a given energy spectrum (Fig. 1). The height or *intensity* of a given peak reflects, in part, the concentration of that element in the sample and may be converted to units of concentration, usually by comparison to a regression line or quadratic algorithm based on well-characterized standards (Jenkins 1999; McCarthy and Schamber 1981).

Traditional destructive XRF analysis of geologic samples requires rigorous and time-consuming sample preparation. Samples are ground to a fine powder and pressed into briquettes or, for analysis of major elements, prepared as fused glass disks, particularly for wavelength XRF (WXRF) where the relationship between the angle of the instrument and the object analyzed is crucial. However, with energy-dispersive XRF (EDXRF) where the emitted energy is captured by the detector for all elements simultaneously, and through a detector and multichannel analyzer convert that energy to pulses and ultimately through software to elemental data, the surface of the object is not as critical (Davis et al. 2011). While early EDXRF instruments did not yield the instrumental precision of WXRF, and certainly neutron activation analysis (NAA), advances in detector electronics and software have decreased the difference between these instruments and with miniaturization have heralded the portable XRF emerging technology (see Liritzis and Zacharias 2011). A number of experiments (summarized in Davis et al. 2011) have shown that EDXRF is the best technique in the analysis of volcanic rocks when sample destruction is not possible (see also Lundblad et al. 2008) (Fig. 2).

The overarching assumption seems to be that XRF, particularly energy-dispersive x-ray fluorescence spectrometry (EDXRF), solves so many of our problems in the archaeological sciences. Glascock (2011) most recently addressed this issue by directly comparing the results of NAA versus EDXRF for obsidian sources in Central Mexico. I refer you to that study for an in-depth discussion on this subject.

What's Good About XRF

The appeal of x-ray analysis of archeological specimens lies in its remarkable combination of practical and economic advantages:

- *Nondestructive*

  In the vast majority of cases, analyzed samples are not destroyed or changed by exposure to x-rays. They can thus be saved for future

X-Ray Fluorescence (XRF): Applications in Archaeology, Fig. 2 Schematic drawing of a typical EDXRF instrument. Cooling can be either electronic Peltier or liquid nitrogen (LN). From Shackley (2011b: Fig. 2-9)

reference or used for other types of testing that may be destructive, such as obsidian hydration analysis.

- *Minimal Preparation*

  Many samples can be examined with little or no pretreatment, including almost all obsidian artifacts. While it is best to wash any sediments off archaeological specimens, it has been shown that if the dirt is minimal, and the artifact has not been subjected to heat so high as to melt some sediment matrix onto the sample, vigorous cleaning is not necessary (Shackley and Dillian 2002). This is mainly due to the penetration of x-rays in the mid-Z x-ray region beyond the surface, and while it does incorporate any contamination on the surface, it is generally not an issue if some soil remains in the flake scars. The analyzed volume is very large compared to any surface contamination. This is not the case with most metals, where patination and chemical weathering can radically change the composition at the surface and yield erroneous results (Hall 1960).

- *Fast*

  X-ray spectrometry enables chemical compositions to be determined in seconds. For an analysis of the elements Ti-Nb on the Berkeley Thermo desktop instrument, at 100 live seconds per sample, it takes about 3 to 5 minutes per sample depending on mass.

- *Easy to Use*

  Modern instruments run under graphical interfacing software that easily handles measurement setup and results calculation. Tasks that once required the constant attention of a trained analyst can now be handled by skilled students and are fully automated after, of course, effective calibration and method compilation.

- *Cost-Effective*

  Without the more involved sample preparation necessary in most WXRF and all

destructive analyses, the cost is significantly lowered per sample.

While this suggests that XRF will solve all our problems, it is not the all-knowing black box we would like it to be, however (Speakman et al. 2010).

What Nondestructive EDXRF Will Not Do

- Sample size limits. Samples >10 mm in smallest dimension and >2 mm thick are optimal for desktop EDXRF analyses (see Davis et al. 2011; Lundblad et al. 2008). Why is this important? Shackley (1989) and more recently (Eerkens et al. 2007) noted that for hunter-gatherers in the North American West, high residential mobility often requires that stone sources, including obsidian, be conserved for long periods of time. As an example, an Archaic hunter will attempt to rejuvenate a dart point rather than make a new one whenever possible as he or she moves through the landscape. The rejuvenation of that point creates debitage that is quite small, often smaller than 10 mm. With modern recovery techniques, these small debitage are recovered much more often than they were in the past, and to make a long story short, Eerkens et al. (2007) found that indeed these small obsidian flakes in North American Great Basin sites indicated not only greater distance to the original tool raw material but a greater diversity of sources than visible with an analysis of the larger flakes with EDXRF. So, while EDXRF can analyze much of the stone material left in prehistory, it may not solve all problems of interest to twenty-first-century archaeologists. To be fair, however, the procurement ranges that could be reconstructed were relatively accurate with samples above the 10 mm threshold in the Eerkens et al.'s (2007) study, and NAA had to be used on the smaller flakes which is essentially a destructive technique. Recently, however, with the newer digital EDXRF instrumentation and tube collimation, we have been able to reach sizes down to 2 mm with the ThermoScientific Quant'X EDXRF at Berkeley, and the "spot" sizes on many portable instruments are much smaller enabling the analysis of small debitage.
- Restricted elemental acquisition: As discussed below, nondestructive XRF is restricted generally to a subset of the mid-Z x-ray region; the best portion including Ti-Nb contains excellent incompatible elements for volcanic rocks (Shackley 2005). While some rare earth elements and those with low atomic numbers or with very low concentrations can be useful in discriminating sources, in most cases, XRF cannot solve that problem. This is discussed in detail in Glascock's comparison between XRF and NAA (2011).
- XRF cannot characterize small components – XRF like NAA is a mass analysis – every component in the irradiated substance is included in the analysis. It is possible to collimate the incoming x-rays from the tube and/or into the detector to focus on small components such as various minerals, but environmental scanning electron microscopy (ESEM), electron microprobe, or laser ablation inductively coupled plasma mass spectrometry (LA-ICP-MS) is much better suited to this kind of analysis. However, the bulk analysis of volcanic rocks has shown to be quite effective.

It is true that XRF will not solve all our problems in archaeological provenance studies; it is simply the best nondestructive analytical tool at our disposal at this time (see Shackley et al. 2017).

Is pXRF a Revolution or Just the Latest Development in XRF?

While portable XRF has both become very popular and highly criticized, this is expectable in a discipline that borrows much of its analytical technology (Liritzis and Zacharias 2011; McAlister 2011; Shackley 2011a, b; Sheppard et al. 2011; Speakman and Shackley 2013). What seems to be most problematic is that these portable instruments were originally designed for mining and industrial applications seeking only qualitative results. These methods and calibration

are not necessary and sufficient to address archaeological problems where relatively precise quantitative data are required. Tied to this, most of the instruments, unlike lab/desktop EDXRF, did not allow the user to generate their own calibrations, indeed most relied solely on fundamental parameter routines that are often standardless and could not be modified beyond factory settings. The criticisms have had their effect, and many of the manufacturers are generating software that allows the user to employ linear calibrations by ratioing peaks/counts to the Compton scatter and thus eliminate the problem of differing sample sizes as earlier discussed by Davis et al. (2011) and Lundblad et al. (2008) for lab EDXRF instruments. Given these important shifts in the ability of pXRF, it will be possible to take a sensitive instrument to the field or museum settings and nondestructively analyze at least volcanic rocks with similar instrumental precision and accuracy of lab XRF instruments. Most of the pXRF systems now available do not acquire the range of elements that laboratory systems do (i.e., Na through U), but the mid-Z (i.e., $Z = 19–41$) sensitivity seems to be very good. There may come a time in the near future when portable systems will acquire the typical sodium through uranium elements that laboratory instruments can today, but they are not here yet (c.f. Liebmann 2017). This is likely the future of XRF in archaeology. Hopefully, archaeologists will evaluate it with the same skepticism that is healthy for the discipline.

Introduction

The site of Yafteh is a well-shaped Karstic cave that had been used as a base camp by the Upper Paleolithic hunter-gatherers of Khorramabad valley of Central Zagros between 29,000 and 39,500 years ago. The Yafteh cave is one of the main reference sites of Iranian Upper Paleolithic which has yielded a well-dated archaeological sequence and several large assemblages of lithic artifacts, faunal remains, and considerable number of symbolic objects (Otte et al. 2007, 2012; Shidrang 2015, 2018; Mashkour et al. 2009). The lithic industries of this site are relatively well defined from both typological and technological points of view and may be considered as the best representative of Baradostian/Zagros Aurignacian culture in the region. Yafteh cave is located at about 13 km to the West of Khorramabad (33^0 33'30"N, $48^0$12'41"E) in Lurestan province, western part of the central Zagros (Fig. 1).

Definition

Yafteh cave is a part of the karstic system in Mesozoic and Cenozoic limestone formations of the folded zone in the central Zagros and located on the piedmonts of a mountain ridge with the same name which is a part of the higher Sefid Kuh mountain range (Hole 2012; Otte et al. 2007, 2011). Yafteh is located at an elevation of 1278 m above sea level and is a south facing cave with a good panoramic overview of an alluvial plain or in fact a part of Khorramabad valley (Hole 2012).

The interior of the cave is an elongated chamber with maximum dimensions of 22 × 9 m, and its entrance measures about 10 m wide and 4 m high which opens toward southwest and connect to the valley floor with a gentle slope (Fig. 2). In addition to its perfect topographic location, several excavations at Yafteh cave revealed a wealth of Paleolithic archaeological remains, specifically from Upper Paleolithic period, that led the researchers to consider the cave as an Upper Paleolithic base camp (Hole and Flannery 1967; Hole 2012).

Key Issues and Current Debates

The Yafteh cave excavated for the first time by Frank Hole in 1965 as a part of a Prehistoric survey project he conducted with Kent Flannery in Khorramabad valley, southwestern Iran. The

Yafteh Cave, Fig. 1 Map showing the location of Yafteh cave in the central Zagros. (After Otte et al. 2007)

excavation revealed two meters of Pleistocene deposits containing mainly the archaeological evidence of Upper Paleolithic period. Eleven radiocarbon dates obtained from 1965 excavation in Yafteh cave and most of the samples failed between 29,000 and 38,000 BP with an early date of 40,000 BP which attracted many attentions to the site (Hole and Flannery 1967).

Yafteh Cave, Fig. 2 Yafteh cave opens at the top of a gentle slope and offers a panoramic view of the alluvial plain of Khorramabad. (Photo: S. Shidrang)

The richness of archaeological materials discovered from the Khorramabad excavations permitted Hole and Flannery to detect the diachronic changes in the lithic artifacts found from the Late Mousterian to the Zarzian layers. Based on these investigations, they defined two subdivisions for the Upper Paleolithic lithic industries or Baradostian and also proposed the hypothesis of gradual development of the Late Mousterian industry into Baradostian in this region. According to these studies, the Baradostian lithic industry of the Yafteh cave displayed an increase in tool types and blade production, but the subsistence pattern did not show a great difference between the two periods (Hole and Flannery 1967).

During last four decades the lithic assemblages of Yafteh cave examined by several researchers, among them the reexaminations of the Yale University collection by Minzoni-Déroche, Otte, Kozlowski, and the National Museum of Iran's collection by J-G. Bordes and S. Shidrang, led to the better understanding of the typo-technological characteristics of these industries and highlighted their resemblance to the Aurignacian industries of Europe and Levant (Minzoni-Deroche 1993; Otte and Kozlowski 2004; Bordes and Shidrang 2004, 2009).

In 2005, a new test excavation at Yafteh cave by Otte and Biglari and then by Otte and Shidrang in 2008 provided new AMS dates for the Baradostian sequence of Yafteh cave (Otte et al. 2007, 2011, 2012; Shidrang 2007b). New chronological data lunched the possibility of intermediate chronological position of the Baradostian or Zagros Aurignacian (the term coined by Olszewski and Dibble in Olszewski and Dibble 1994) in southwest Asian Early Upper Paleolithic sequence which may overlap with the Early phase of Ahmarian and predate most of the dates of Levantine Aurignacian. These dates suggested the attribution of the sequence to an age between 24,500 and 36,000 14C BP and launched the probability of a single chronological signal of approximately 33,500 14 C BP for the major part of the Yafteh sequence (Fig. 3) (Otte et al. 2011).

Besides chronological investigations, the study of the 1965s Yafteh Collection by Bordes and Shidrang in 2004 updated the state of knowledge on the techno-typological evolution of the Baradostian industry and its place in the debate of Aurignacian technocomplexes (e.g., Bordes and Shidrang 2009). Bordes and Shidrang's work was inspired by the late 1990s ongoing

Yafteh Cave, Fig. 3 Table summarizing 14C ages and calibrated results (Otte et al. 2011)

research on the appearance of the Aurignacian culture and the dispersal of Anatomically Modern Humans in Europe through the tracing of the two earlier industries of the Aurignacian classification (e.g., Bon 2002, 2006; Bordes 2002, 2006; Bazile and Sicard 1999). The 2004 study established a

new comparative framework for the Baradostian with other similar industries and increasingly put the emphasis on its resemblance to the Proto-Aurignacian of Europe and in part to the early Ahmarian of the Levant.

In the Baradostian sequence of the Yafteh cave, the lower part of the sequence is associated with an assemblage mainly oriented toward the production of Arjeneh points and relatively large, straight, or slightly curved Dufour bladelets. The bladelets or blanks of these tools were removed from prismatic cores or sometimes from narrow flake ridges. There are also a number of end-scrapers on blades which in some cases have Aurignacian retouch on their lateral edges (Fig. 4). The later phase of the Baradostian sequence in the Yafteh cave is characterized by the production of small twisted bladelets produced from carinated burins and nosed scrapers made mostly on cherty nodules and having fine and semi abrupt inverse or alternate retouch (Roc-de-Combe sub-type Dufour bladelets) (Fig. 5), which resemble the later phases of Aurignacian or the recent Aurignacian (Bordes and Shidrang 2009; Shidrang 2015, 2018).

A recent analysis of 2005–2008 Yafteh lithic assemblages combined with stratigraphical interpretations and information derived from other archaeological materials, suggested a three cultural phases model for the Yafteh sequence (Shidrang 2015, 2018). The oldest phase contains a lower frequency of artifacts, and the main technological characteristic of the assemblage is a few number of standard flat prismatic cores that their negatives of removals correspond to bladelets with a very straight profile and most probably moderate size blades from the initial stage of the reduction sequence. The toolkit is relatively simple including Baradostian bladelets type A (Dufour bladelets of Dufour subtype), Arjeneh points and retouched bladelets with a few retouched blades. Despite the limited number of artifacts in this phase, the tools percentage ratio to debitage is fairly high which may suggest the earliest phase of the sequence corresponds to short-term visits of EUP hunter-gatherers to the site rather than a long seasonal occupation (Shidrang 2015, 2018). The central phase of the Yafteh sequence is the main and probably the longest occupation of the site. This rich layer contains significant amount of archaeological materials, and it has an ashy texture with charcoal, visible fire place, and frequent traces of ocher. In the middle phase, blades increase (a separate line of blade production?) and frequently used as blank for end scrapers, notches, or typical Aurignacian retouched blades. There is a diversity of bladelet cores which display some degree of specialization for production of different bladelet types. Carinated burins that are an important characteristic of the upper phase or the last EUP occupation of the cave appear in the upper part of the middle phase. Among other elements, a considerable number of Arjeneh points as well as end scrapers on blades might indicate a base camp occupation specialized in hide working and piercing hides and ornaments in the middle phase of the sequence. While having many Proto-Aurignacian similarities in the earliest phase, the middle phase of the Baradostian in the Yafteh cave has been transformed into a more complicated industry with more diverse and intense specialization of tools (Shidrang 2015, 2018).

The small bladelets with twisted profile which were usually produced from carinated burins appear from the middle phase but increase in the upper part of the sequence. The small twisted bladelets mainly had no retouch, but some were retouched into Type "B" Baradostian bladelets or Dufour bladelets "Roc de Combe" subtype (Fig. 5). Contrary to bladelets which are frequent in the late phase, blades are less standard and lose their importance as the primary choice for end scrapers, being replaced by flakes. All these characteristics resemble the late Aurignacian of Europe which has received less attention compared to Early Aurignacian (Shidrang 2015, 2018). The Yafteh cave excavations yielded considerable evidence of personal ornaments, bone tools, and frequent use of ocher and other minerals throughout the sequence of Baradostian (Otte et al. 2007; Shidrang 2007a, 2015). Such evidence is completely absent in the Middle Paleolithic of the Zagros, and their presence in the early Baradostian may point to a considerable cultural differences between the behavioral patterns of the Middle and Upper Paleolithic hunter-gatherers in the Zagros (Shidrang 2015, 2018).

Yak: Domestication

Jianlin Han
CAAS-ILRI Joint Laboratory on Livestock and Forage Genetic Resources, Institute of Animal Science, Chinese Academy of Agricultural Sciences (CAAS), Beijing, China

Basic Species Information

The domesticated yak (*Bos grunniens* Linnaeus, 1766) is a bovine species with unique long hairy skirts on its chest, flanks, and rump as well as a fully haired and horse-like tail. There are ~14 million domestic yak distributed at high altitudes from 2,000 to 5,000 m accompanied by hypoxia and low temperatures throughout the Qinghai-Tibetan Plateau, Himalayan and Altai regions in Asia. Yak is the most important livestock species for the nomads, mainly the Tibetans, in the region given their importance in producing meat, milk, fiber, hide, dung fuel as well as pack energy (Olsen 1990; Wiener et al. 2003; Leslie and Schaller 2009). The wild yak (*Bos mutus* Przewalski, 1883) survives in remote northern Qinghai-Tibetan Plateau at elevations from 3,000 to 5,500 m. The number of wild yak has shrunk from millions to less than 15,000 in the last century due to poaching and competition with livestock. This led to isolated and fragmented habitats with major populations present in northern Tibet and western Qinghai provinces, China. Yak are recognized as vulnerable among the IUCN Red List of Threatened Species (Olsen 1990; Wiener et al. 2003; Leslie and Schaller 2009).

The extant wild yak is thought to be the direct ancestor of the domestic yak. The domestication process may have begun ~10,000 years ago by the ancient nomadic Qiang people. The establishment of a primary yak industry and culture in China started at least 4,500 years ago. However, the taxonomic classifications and scientific names of both domestic and wild yak have gone through various changes under the genera of *Bos*, *Poephagus*, and *Bison*, mostly based on limited morphological and anatomical descriptions.

Apart from the hairy skirts, yak has 14 dorsal vertebrae and 14 pairs of ribs which are one and one pair more than other bovine species but five lumbar and 12–16 coccygeal vertebrae which are one and four to zero less than other bovids, respectively (Olsen 1990; Wiener et al. 2003; Leslie and Schaller 2009). Although the yak shares the basic vertebral column structure with American bison and European wisent following their probable common and recent past ancestry in central Asia (Leslie and Schaller 2009), Olsen (1990) found some anatomical difference in their skulls. There have been some reports on bovid fossil related to ancestral yak, but Olsen (1990) challenged their taxonomic assignments based on fragmented specimens excavated from Pleistocene locations in Alaska of USA, China, India, Nepal, and Russia. In the documentation of most but limited archaeological and recent historical evidence in China, Olsen (1990) concluded that the fundamentals of when and how yak domestication began remain obscure.

Guo et al. (2006) and Qi et al. (2008) investigated the genetic origin of domestic yak using variations in mitochondrial DNA (mtDNA). In two separate datasets, the former with only Chinese yak samples and the latter with a complete sampling across all eight yak keeping countries in Asia, two or three deeply divergent (>100,000 years before present) and diversified phylogenetic mtDNA lineages were observed. The major lineages were shared by domestic and wild yak while there was no clear geographic structure in terms of the distribution patterns of the major mtDNA lineages among domestic yak populations, supporting a single and recent origin of domestic yak from wild yak gene pool. Molecule dating of the major lineage (mt-I) from Qi et al. (2008) suggested an expansion of domestic yak population ~5000 years ago, which largely agrees with available archaeological evidence for yak domestication (Wiener et al. 2003). Different refuge wild yak populations harboring the

mtDNA lineages were thought to have survived over the most recent glacial period when the Qinghai-Tibetan Plateau was not completely covered by ice. Such populations intermixed before domestication and thus contributed to the unique mtDNA diversity reservoir in today's domestic yak.

The highest mtDNA diversity and a significantly expanded major lineage (mt-I) identified in the eastern Qinghai-Tibetan Plateau area advocated it to be considered as the primary center for a single domestication event for yak. Two separate dispersal routes were testified following the significant but gradient reduction in mtDNA diversity in domestic yak populations distributed along a westward route via the "Pamir Knot" across the Himalayan and Kunlun mountains and a northward route across the South Gobi and Gobi Altai mountains (Qi et al. 2008). An extended Chinese yak mtDNA D-loop dataset and complete mtDNA sequences confirmed the previous findings and revealed a unique haplogroup present in wild yak (Wang et al. 2010).

The hybridization of female yak crossing with local male taurine (*B. taurus*) or indicine (*B. indicus*) cattle has been practiced since 1100 BCE and this practice intensified in the mid-1900s in order to explore the heterosis in milk and meat performance. The F1 yak-cattle hybrids are called Pien Niu by the Chinese, of which the females are fertile but males remain sterile until the third generation of backcrossing (Wiener et al. 2003; Qi et al. 2010). Molecular marker–based analyses revealed cattle introgression in most of domestic yak populations in Asia and a higher cattle admixture was detected among the Chinese and Mongolian yak populations than those kept in the Himalayan region and Pamir Plateau area (Qi et al. 2010). Wild and domestic yak can interbreed to produce fertile offspring of both sexes, and semen collected from the tamed wild yak bulls has been successfully applied to improve domestic yak genetics since 1990s in China (Wiener et al. 2003).

Recently, the draft genome assembly of a female domestic yak was published based on a whole-genome shotgun sequencing strategy at 65-fold coverage with a total length of 2,657 Mb base pairs. Comparative analyses between the yak and cattle genomes revealed that yak carried expanded gene families responsible for sensory perception and energy metabolism as well as enriched protein domains related to sensing extracellular environments and hypoxic stress, which were found to be under positive selection in evolution (Qiu et al. 2012). These findings are important to understand the unique adaptability of the yak to high altitudes. Such genome resources would certainly facilitate the identification of genes and alleles for genetic and genomic selection to improve the productivity of yak.

Yamanouchi, Sugao

Makoto Tomii
Centre for Cultural Heritage of Kyoto University, Kyoto, Japan

Basic Biographical Information

Sugao Yamanouchi (1902–1970) was a Japanese archaeologist, often called the "Father of Jomon studies". Jomon is the name of the Japanese hunter-gatherer period/culture with pottery. Yamanouchi was born in Tokyo in 1902, the son of the teacher of Japanese literature. In 1914, he entered Waseda Junior High School (in the old system of education, almost equal to the high school in the present educational system). During his school days, he was interested in evolution and Marxism/anarchism and read *On the Origin of Species* by Charles Darwin and *Das Kapital* by Karl Marx, in their original languages. He also had fun collecting artifacts on some archaeological sites, including Jomon shell middens, and sometimes had a chance to talk with the famous anthropologist, Ryuzo Torii in the University of Tokyo, who was a lecturer at that time.

In 1919, following Dr. Torii's advice, Sugao Yamanouchi chose to enter not high school but the college course of the Department of Anthropology at the University of Tokyo (in the old system of education, almost equal to the half stage of an undergraduate degree in the present educational system). As an undergraduate, he had a great interest in genetics, and his bachelor thesis was based on the subject. In 1922 he graduated from the college course. He worked at Tohoku University, located in the northeast part of Japan, as a junior assistant of the Department of Anatomy from 1924 to 1933. Over the period of a decade, he excavated a large number of shell middens – including those at Daigi-gakoi, Obora, and Satohama – in order to accumulate data for the sequential stratification of Jomon pottery. His ambition was to construct a chronological framework for Japanese prehistoric pottery, in order to establish the sequence of human skeletons of prehistoric Japan. However, Yamanouchi gradually came to dislike his job in the department because of its hierarchic nature, and because he held a sharply divided opinion on genetics, which was against that of the department professor, Kotondo Hasebe, he resigned his post in 1933. Yamanouchi decided to remain as an archaeologist with no formal institutional affiliation. After returning to Tokyo, he began to hold study meetings on prehistory, and these produced a journal, *Senshi Koko-gaku* (*Prehistoric Archaeology*), which continued for several years.

In 1946 Yamanouchi was appointed as a lecturer with the Department of Anthropology at the University of Tokyo, probably because of a collapse of imperialism due to the defeat of World War II. Yamanouchi served as a member of a number of committees of the Japanese Archaeological Association, which was the first nationwide organization of archaeology, from the time of its inception in 1948. In 1962, he received a doctorate from Kyoto University, and on the very same day, he left the University of Tokyo upon reaching retirement age. After that, Yamanouchi joined the Department of Arts and Literature of Seijo University as a professor of culture history. In the summer of 1970, he died by pneumonia.

Major Accomplishments

Sugao Yamanouchi's major accomplishments include identification of the impression of cord mark – which is meant by the Japanese word, "*Jomon*" – on pottery in Japanese hunter-gatherer culture. Consistent with its literal sense, Jomon pottery mostly has cord impressions. The wide range of variation in cord impressions in Jomon pottery serves as a key to determine the local pottery type or to subdivide the chronological sequence of a local pottery tradition. Prior to

Dr. Yamanouchi's work, this decorative technique had long been unsolved. Dr. Yamanouchi solved the riddle no later than 1929 (Saito and Sakadume 1998), by showing that, in most cases, the cord mark was produced not by the mere impression of cords but by rolling either a cord or a wound strand around a shaft.

Dr. Yamanouchi was the first scholar to attempt to construct the chronological chart of Jomon pottery sequences in type and to apply this throughout the Japanese mainlands. When he excavated the Ogawa shell midden in Fukushima in 1924, he fully recognized the importance in the stratigraphical evidence which he had already known from Dr. Matsumoto's work on typological sequence of Jomon pottery based on the stratigraphical data from the two shell middens – Satohama and Usozawa – excavated in late 1910s (Matsumoto 1919). Then, Yamanouchi gradually devoted himself to research in Jomon pottery sequence. It is true that he did not come back to anatomical analysis which would rely upon the time measure proposed by him of pottery sequences, while every scholar of Jomon culture has relied basically upon his framework of the sequence since his work. In 1930s, his chronological investigation clarified the almost simultaneous introduction of rice farming throughout the main parts of Japanese Archipelago. In Japanese prehistoric studies, since then, the argument for rivalry ceased to be operative between the western Japan as earlier rice cultivation areas and the eastern Japan as delayed cultivation areas deeply based on fishing, hunting, and gathering.

Dr. Yamanouchi's detailed research shed new light on the question of subsistence in Japanese prehistory. In 1925, he identified a rice impression on stone-age pottery (Yamanouchi 1925), which he typologically dated to the beginning of Yayoi period. His work demonstrated that rice cultivation was introduced in the Japanese Archipelago during the Yayoi period. This interpretation was put forward at a time when most archaeologists believed that rice cultivation did not start until the introduction of metal. Later, Dr. Yamanouchi hypothesized that salmon and nuts had served as staple food in the diet of the Jomon period in the eastern Japan and that this enabled people to achieve prosperity, in contrast to western Japan where salmon hardly existed. Dr. Yamanouchi's hypothesis derived from ethnographic analogies with salmon exploitation by Indigenous groups in California, USA. This is an example of his broad knowledge of world prehistory and ethnography. It is an irony, however, that his understanding of Russian prehistory prevented him from accepting radiocarbon dates for Jomon pottery. He had rejected the idea that the early Jomon pottery dated back to earlier than 5000 BP, since this was not supported by his typological studies of stone implements in Japanese Archipelago and the Russian continent. He did not accept radiocarbon dating unless it was supported by comparison between artifacts themselves.

Dr. Yamanouchi placed much importance on academic freedom throughout his academic career and paid keen attention to the priority of scholars as to who proposed a new theory. He often fiercely criticized other scholars who he thought encroached on his intellectual territory. His frankness led to a number of scholars having difficulties with him. However, there are many archaeologists who are proud to be known as his follower. Sugao Yamanouchi's eventful life with its outstanding and varied accomplishments in archaeology has become almost a legend within the history of prehistoric studies in Japan.

Yams: Origins and Development

Huw Barton
School of Archaeology and Ancient History, University of Leicester, Leicester, UK

Basic Species Information

Yams are flowering plants of the family Dioscoreaceae, consisting of more than 800 species of climbing vines and woody shrubs. Many members of the yam family produce subterranean tubers or tuberous stems, and have heart-shaped leaves, small green or white flowers, and a fruit that is a winged capsule or berry. Yams are distributed widely throughout the tropical and warm temperate regions of the world, though current geographic distribution has almost certainly been influenced by human translocations. Today yams are widely used as an important food staple and as a fallback food in Africa, Asia, the Caribbean, Pacific islands, and South America.

In 2007, worldwide yam production totaled 52 million t, of which Africa produced 96%, most of which derived from West Africa, with Nigeria alone producing 71% of that total (IITA 2009). Yams are a good source of dietary fiber and are rich in carbohydrates, vitamin C, and essential minerals. Yams may be stored for up to six months after harvest, making them ideal for transport, and can be consumed by boiling, roasting, baking, frying, mashing, and even processing into flour, which will keep for prolonged periods. Spanish and Portuguese mariners added Southeast Asian yams to their ship stores transporting several species of Dioscoreas to the New World. The word yam is thought to derive from West African languages, from the Mande, *niam* or the Temne, *enyame*, later adopted into Portuguese as *ynhame* and Spanish as ~ *tame*, French, *igname*, and English as, *yam* (Burkill 1938). While the term "yam" is now used loosely to refer to many different genera that produce edible roots, true yams are only those of the family Dioscoreaceae.

Harvesting wild yams is a relatively simple procedure; several groups employ the use of a digging stick, such as the Sakai of Malaysia, Baka of Cameroon, and the Aborigines of Australia. Collection of tubers from a wild plant will disturb the soil, aiding in the growth of new tubers and larger tubers, and as long as the growth head of some tubers is left behind, the plant will continue to produce fresh tubers, providing foragers with a perennial resource. The Baka also fill the hole left behind with organic matter to facilitate new yam growth. This simple vegetative mode of propagation also allows for in situ management of yam plants by foragers. Transport of yams from their place of collection to campsites, or settlements, will have inadvertently spread

useful yams along with the dispersals of people. In some parts of the Pacific, deliberate translocations of yams to "seed" new islands may have been an important element of human colonization of these and other landscapes.

Human Evolution

Several hypotheses have been proposed where yams and other plants producing edible starchy roots (collectively described as Underground Storage Organs, USOs) are key to the spread of hominins outside Africa and of important changes in social organization. Wrangham et al. (1999) have suggested that access to USOs and cooking them, which dramatically increasing digestibility and energy returns, was a key evolutionary factor in the reduction of molar and gut size of *Homo erectus*, and helped facilitate dispersal of that species.

The "grandmother hypothesis" forwarded by O'Connell et al. (1999) suggests that instead of males provisioning the group with meat (a high-risk strategy of potentially high energetic returns, but with low rates of success), women and daughters supplied the group with USOs (a low-risk resource with high energetic returns). In doing so, this engendered mother-infant food sharing, combined with assistance from grandmothers, reinforcing co-residence among related females. As a result, it is suggested that matrilocality may have been the dominant model of hominid social organization throughout most of the Lower and early Middle Pleistocene (1.8– < 0.5 myr) (O'Connell et al. 1999).

The oldest remains of yam tissues in an archaeological context come from the West Mouth of Niah Cave in the lowland rainforests of Sarawak, Malaysia. From several deposits dating to 20,000 years ago, fragments of the yam *Dioscorea hispida*, and other unidentified tuberous remains were recovered by flotation (Barton and Paz 2007). *Dioscorea hispida* is still an important food source in Island Southeast Asia today among forager groups on the Malay Peninsula, and as a fallback food across island Southeast Asia. What is so interesting about this plant though is its toxicity. Without treatment, usually soaking, boiling, and/or roasting, the tubers are extremely toxic and cases of accidental death or hospitalization are known. Access to toxic yams could have provided important evolutionary advantages to humans, providing them with a relatively rewarding food source, isolated from other competitors, such as pigs and large ungulates.

Fire Management

Aboriginal Australians used fire as a tool to encourage the distribution of yams and manage productivity. The Kuku-Yalanji people of Cape York, Queensland, exploited two species of yam, *Dioscorea bulbifera*, and *Dioscorea transversa*, burning rainforest margins to encourage growth (Hill and Baird 2003). In Western Australia, *Dioscorea hastifolia*, was also managed by the use of fire, increasing the density of this plant in specific areas (Hallam 1989). In eastern Australia in 1841, Governor Sir George Grey noted large tracts of land studded with holes where people had been extracting yams (possibly *Dioscorea transversa*). Continuous digging around some species acts to aerate the soil, thin and encourage better growth, and burning provides disturbed habitats that favor certain species (Gott 2005).

Domestication

Some groups of West African farmers engage in a process of yam management, rather loosely referred to as a process of "domestication" (Dumont and Vernier 2000; Scarcelli et al. 2006). Farmers select yam tubers from the forest that present desirable phenotypic attributes such as size, color, and taste and transplant the yam head, from which new tubers grow, into their cultivated plots. Over a period of 3–4 years, farmers can induce favorable change in the tubers (Hildebrandt 2003) by various methods including through applying stress by increasing the harvesting cycle; exposure of plants to sunshine, tillage, and mound heaping (Chikwendu and

Okezie 1989; Scarcelli et al. 2006); and, also by the introduction of an obstacle, such as a stone or piece of pottery, that physically interfere with the orientation of tuber growth (Vernier et al. 2003: 39). Simply harvesting the plant repeatedly changes the soil conditions around newly forming tubers, allowing the growth of larger tubers in more loosely packed soils (Hildebrandt 2007: 290). If the phenotypic changes are of interest to the farmers, these plants are then introduced into the main crop, often alongside tubers with similar phenotypes (Scarcelli et al. 2006: 122).

The entire process is managed entirely via vegetative propagation though the exact biological process allowing this plasticity of tuber form is unknown (Scarcelli et al. 2006: 122). In order to better understand this process, Scarcelli et al. (2006) undertook a genetic analysis of "wild" (in their terms) "predomesticated" plants (*D. abyssinica* and *Dioscorea praehensilis*) that reproduced sexually from the forest with cultivated varieties (*D. cayenensis*, *D. rotundata*) that were vegetatively propagated. They found that nearly half the samples (47%) considered to be "wild" contained genes from cultivated "domesticated" yams and that 14 samples could be considered genetically intermediate between the "wild" and "domesticated" plants. Sexual reproduction maintains genetic variation that is gradually incorporated into cultivated plots where propagation is continued via asexual methods. The mixture of genes from "wild" and "domesticated" varieties suggests ongoing hybridization, probably from feral plants abandoned in old fallows that have since returned to forest (Mignouna and Dansi 2003: 524). Farmers select from a mixture of heterogeneous genetic stock consisting of wild species, a diversity of hybrids, and feral landraces from old farms (Mignouna and Dansi 2003: 527).

Genetic studies of African yams show that there are no clear genetic and phenotypic correspondences between yams classified as "wild" and "domesticated." The processes employed by people in the selection and propagation of yams can lead to useful phenotypic change, but with little corresponding genetic change (Mignouna and Dansi 2003; Zohary 2004; Scarcelli et al. 2006).

Toxins and Medicinals

The active compounds within the family of Dioscorea yams fall into three main categories: the alkaloids, tannins, and saponins (Coursey 1967). The tannins and saponins are the least likely to present a problem for human consumption, though they do affect the taste of the tuber. Tannins are thought to give tubers an acrid taste (Coursey 1967: 208) and the saponins cause bitterness (Coursey 1967: 210). Saponins have also been identified as the active component in many fish poisons (acting to deoxygenate the water) and are readily detectable in tubers, characteristically forming a soapy lather when agitated in water (Coursey 1967: 209). At least one of the alkaloids, dioscorine, which has been identified in *Dioscorea hispida*, is extremely toxic and causes paralysis of the nervous system and – if taken in sufficient quantities – death (Burkill 1966: 833). While some of the chemicals and cellular crystals in tubers and rhizomes cause discomfort, the toxins and other physiological effects are usually destroyed or alleviated by heat, applied either through boiling or roasting.

Many groups exploit yams for their medicinal properties. In China's Yunan Province, the root of *Dioscorea althenoides* is taken orally as a cure for chronic rheumatism, indigestion, and for injuries from falls (Huang et al. 2004). Among the Lahu of Southwest China, the leaves of *Dioscorea bulbifera* are used as an antiseptic for puncture wounds and a decoction from the mature fruits to alleviate gastric bleeding (Huai and Pei 2004). In India, *Dioscorea bulbifera* is used as contraceptive by some tribal groups. *Dioscorea pentaphylla* is used as a medicine for ailments of the digestive tract and for problems with respiration. *Dioscorea prazeri* may be used as a soap and shampoo to kill lice. The pounded leaves of *Dioscorea hispida* may be used to treat skin conditions in Malaysia. Among the Sakai of Peninsular Malaysia, mucilage from the tubers of *Dioscorea laurifolia* and unidentified *Dioscorea* species is used to treat warts. The boiled tubers of *Dioscorea membranacea* are used to treat asthma and fever (Maneenoon et al. 2008).

Social Contexts of Yams

The Baka of Cameroon apply the metaphor of the human body to describe the anatomy of yams; it is the only plant treated in this way (Dounias 1996). The spiny roots at the head of the tuber are referred to as "hair," the oblong tuber as "body," and the terminal point as "bottom." Other tuberous forms are associated with male reproductive organs and leaf hairs are recognized as human "body hair" (Dounias 1996: 624). Ownership of newly discovered plants is marked by snapping vegetation surrounding the plant. Underground cavities left by the extraction of yams, which may last for years, are recognized by a name which translates as "edible yam ancestor" (Dounias 1996: 629).

Amongst the Avatime of Southeastern Ghana, yam rituals involve feeding the "forebears" before any living member of the clan may eat the yam flesh (Brydon 1981). These yam rituals are not held for the entire village but are reserved for kinship groups: "It is the elders of the clans who are the representatives of the living Avatime and who must make sure that the spirits of the clan forebears are well looked after before they eat yams themselves" (Brydon 1981: 666).

On the island of Pohnpei in Micronesia, yams are also revered and cultivated as a high prestige food. The islanders cultivate at least 133 varieties of *Dioscorea* species, though total agrodiversity is thought to have increased dramatically over the last 150 years with introductions by whalers, traders, missionaries, and colonial administrators, as well as Pohnpeians returning from overseas (Raynor et al. 1992). Traveling with your yam was clearly the thing to do. Consumption of yams on Pohnpei is a strongly ritualized activity where humans may not eat yams until they have been presented to the island chiefs, and through them, to the various traditional gods.

Yellowhorn, Eldon

Eldon Yellowhorn
Department of Archaeology, Simon Fraser University, Burnaby, BC, Canada

Basic Biographical Information

Eldon Yellowhorn is a past president of the Canadian Archaeological Association (2010–2012) and the first Aboriginal person to hold this title. It is the latest milestone he has reached during his career in archaeology.

Dr. Yellowhorn grew up on a farm on the Peigan Indian Reserve in southern Alberta, and his boyhood years were full of rural adventures. There is a direct path from the family farmstead to his interest in the earth sciences that inspired his professional development. His undergraduate degrees in physical geography (1983) and archaeology (1986) from the University of Calgary brought him insights about the prairie landscape of his childhood that added more fuel to his curiosity. Gaining a better understanding of the ancient history of his Piikani ancestors compelled him to take on graduate studies in archaeology.

Dr. Yellowhorn discovered his enthusiasm for archaeological fieldwork through the surveys and excavations he conducted as part of his training. After several field seasons and a curator internship, he decided to pursue advanced degrees in archaeology. Attending graduate school at Simon Fraser University in Burnaby, British Columbia, in 1989, gave him the opportunity to mature as a researcher and to study the antiquity of his home community and the culture he inherited from his ancestors. His survey of the Piikani First Nation identified many new sites but more importantly opened up a discussion on a subject that had received no prior attention. His thesis explored the legal status of heritage protection on Indian reserve lands in Canada and interrogated existing legislation for this purpose.

After he completed his M.A. degree in archaeology (1993), Dr. Yellowhorn began working in the heritage consulting industry, conducting impact assessments in advance of terrain-altering activities. This experience brought him an

insider's view of applied archaeology that differed from the research-oriented mode that was standard for graduate school. Although his clients included a variety of stakeholders, he had a special interest in first nations that needed his archaeological expertise.

By 1995 he had decided to pursue an academic career, so began his days as a student at McGill University. He specifically chose that school in order to work with Bruce Trigger. While studying archaeological theory was crucial for elucidating the archaeological record of the northern plains, Dr. Yellowhorn could not ignore the oral narratives that formed part of Piikani culture. His dissertation research directed him back to the old stories he heard in his youth to ascertain whether they could explain archaeological manifestations. One puzzle that caught his attention was the one that mystified researchers concerning the origins of large-scale communal hunting of bison using "buffalo jumps." Examining this question in light of Piikani mythology led him to construct his scheduling breakthrough hypothesis that accounted for the sudden appearance of this type of bison hunting strategy.

Major Accomplishments

Throughout his career, Dr. Yellowhorn has been an advocate of the right of Aboriginal people to be active participants in examining the past through their internal dialogue on the nature of antiquity. His internalist approach brings a self-reflexive quality to field research that enhances this perspective by appropriating the methods of archaeology to pursue internally defined objectives. Given his faculty appointment at Simon Fraser University, where he is an associate professor in Archaeology and Chair of the First Nations Studies Department, he welcomes the opportunity to train Aboriginal students to become competent researchers of their own antiquity and to be well-informed interpreters of archaeological discourse.

York Archaeological Trust

James Symonds
ACASA Archaeology, University of Amsterdam, Amsterdam, Netherlands
Department of Archaeology, University of York, King's Manor, York, UK

Basic Information

The York Archaeological Trust for Excavation and Research Ltd. is one of the largest archaeological units in the UK, with 100 members, 12 trustees, and 198 staff. The Trust's headquarters is at 47 Aldwark, York, North Yorkshire YO1 7BX, UK.

The Trust was founded in 1972, in response to proposals to construct an inner ring road in York. The road was intended to remove through traffic from the ancient walled city in line with government advice on conservation in historic towns (Esher 1968). However, local archaeologists estimated that the road would have a devastating impact on below ground archaeology, cutting through six major Roman cemeteries, two Roman suburbs, areas of Anglo-Saxon and Viking occupation, three medieval suburbs, the site of a priory, and several churches, ancient hospitals, and almshouses (Addyman 1974: 156). The inner relief road was never built, but regeneration within the city in the Aldwark area, and elsewhere, did proceed. This prompted a series of major archaeological rescue excavations on Roman and later sites by the newly constituted York Archaeological Trust (Jones 1984: 132–143).

Major Impact

In the late 1970s the Trust gained international acclaim for its work on deeply stratified urban deposits. York's location between two rivers has led to the accumulation of moist anaerobic layers, which frequently contain well-preserved organic residues such as fragments of wood, thatch, coprolites, beetles, seeds, and pollen. The excavation of such richly organic deposits enabled the Trust

to undertake pioneering research in environmental archaeology, analyzing the sediments from variety of sites, including a Roman sewer system, in partnership with the Department of the Environment-funded Environmental Archaeology Unit at the University of York (Buckland 1976).

The Trust is perhaps best known for its 5-year-long "Viking Dig" at Coppergate, which revealed tenth-century Viking houses and craft workshops (Hall 1984). The popularity of this dig led to the creation of the Jorvik Viking Centre, which opened in 1984, with its famous time-capsule ride through a reconstruction of the Viking town. In the last 5 years, the Trust has gained prominence by excavating the remains of nineteenth-century working-class terraced houses and shared toilet facilities in the former "slum" area of Hungate. In response to the growth of contract archaeology in Britain, the Trust now operates at a national level, with offices in Glasgow, Sheffield, and Nottingham. The educational activities of the Trust have also grown, and in addition to the Jorvik Viking Centre, the Trust now runs three other attractions in York: Jorvik DIG, an archaeological education and discovery center; Barley Hall, a reconstructed medieval town house; and Micklegate Bar, a medieval gateway containing exhibitions on the city walls (York Archaeological Trust website n.d.).

Yuanmou

Ji Xueping
Department of Paleoanthropology, Yunnan Institute of Cultural Relics and Archaeology, Kunming, Yunnan, China

Introduction

Yuanmou is located in the northern Yunnan Province, near the southeastern margin of the Tibetan Plateau, 110 km away from Kunming, the capital of Yunnan Province, southwestern China. The Yuanmou Basin is a north–south elongated basin ~30 km in length and ~7 km wide on average. It is the lowest basin of the central Yunnan Plateau with an elevation of 1,050–1,150 m. The Longchuan River, the first tributary of the Jinsha River (upper reaches of Yangtze River), runs from south to north and joins the Jinsha River at Longjie town, in the northern part of Yuanmou. The Yuanmou Basin is a faulted basin. The western mountain is comprised of Precambrian metamorphic and granite rocks with an average elevation of 1,400 m, and the eastern mountain is composed of Jurassic and Cretaceous red layered sandstone rocks with an average elevation of 2,500 m; together they comprise the basement rocks of the Yuanmou Basin. The Plio-Pleistocene hominid-bearing fluviolacustrine deposits are best developed in the southern part of the basin and are ~850 m thick and date to between 4.9 and 1.4 Ma (Zhu et al. 2008a). The Late Miocene hominoid-bearing fluvial deposits can be found in the northwestern part of the basin, are ~70 m thick, and date to between 8.5 and 7.1 Ma (Zhang and Yue

2006). The discoveries of hominids and hominoids in the Yuanmou Basin caused great attention from the fields of paleoanthropology and paleontology since 1965.

Definition

In this entry, Yuanmou refers to the Early Pleistocene hominid and cultural remains in Yuanmou Basin, Yunnan Province, Southwestern China.

Key Issues/Current Debates/Future Directions/Examples

Two hominid upper medial incisors were discovered by geologists from the Chinese Academy of Geosciences in May 1965 at a location northwest of Shangnabang village, southeastern Yuanmou Basin. Here, the Plio-Pleistocene deposits are well developed and are designated to the Yuanmou formation geologically. The teeth were unearthed from layer 25, member 4 of the Yuanmou formation (there are 28 layers in total). After comparisons with the hominid material from Zhoukoudian, the original researcher found that the Yuanmou fossils were different from *Homo erectus pekinensis*, and gave it a new subspecies name *Homo erectus yuanmouensis*, represented by a young male individual (Hu 1973, Fig. 1). Subsequently, further study has been carried out and summarized the features as follows: The crown is robust and the outline is triangular fan-shaped, widely expanded to incisive margin; most of the labial side of crown is flat, except the basal part is more convex; and there are Tome's line, labial grooves, and shallow depressions. The basal tubercle and fingerlike projections were developed, the lingual surface shows a distinct shovel fossa which is divided by the median ridge into two halves, numerous enamel furrows are visible in the lingual fossa, and the transverse section at the neck art of the root is nearly elliptical, thinner in labiolingual diameter of root. Generally, it indicates more primitive features than *Homo erectus pekinensis* and shows transitional features between slender *Australopithecus* and *Homo erectus* (Zhou and Hu 1979; Zhou 1998).

A field team from the Beijing Natural History Museum surveyed at the southern slope of Guojiabao site, some 250 m away from the original place where the Yuanmou incisors were found. In December, 1984, a human left tibia shaft was unearthed from fluvial deposits that overlie layer 25, member 4, Yuanmou formation (Zhou et al. 1991; Fig. 2). The tibia should be from layers between 25 and 28, member 4. According to the latest paleomagnetic results (Zhu et al. 2008b), the age of the tibia should be at least 1.4 Ma or between 1.7 Ma and 1.4 Ma. The features of the tibia were summarized by the original researcher as follows: The tibia probably represents a young female and belongs to the platycnemic type. The anterior border of the shaft is obviously round and obtuse, and the

Yuanmou, Fig. 1 Upper medial incisors of *Homo erectus yuanmouensis*. (From Zhou 2009 with permission)

Yuanmou, Fig. 2 Tibia of *Homo erectus yuanmouensis*. (From Zhou 2009 with permission)

S-shape curve is weakly developed. There is a shallow interosseous crest. A marked flexor longus swells behind the shaft, a popliteal line shapes well, and a vertical ridge bulges, dividing the back of shaft into two halves. The wall of shaft is thick and the marrow cavity is relatively small. In general, although from younger layers, the tibia could still be attributed to *Homo erectus yuanmouensis*, the traits approximate *Homo habilis* (Zhou et al. 1991; Zhou 1998).

A formal excavation was launched by the Institute of Vertebrate Paleontology and Paleoanthropology, Chinese Academy of Sciences, at a small hill where the human teeth were unearthed in October–December, 1973; no more hominid fossil have been discovered, but six artifacts were sorted from in situ strata and another ten artifacts were collected from the surface nearby (Yuan et al. 1984). The artifacts were made from quartz and quartzite cobbles and pebbles from rivers. The flaking technique and secondary work of the implements are nearly all undertaken by direct hammering. A few implements were made by bipolar technique, but there are no prepared platforms. All artifacts are small types, and core scrapers are common. In general, those artifacts show features of the early stage of the Early Paleolithic period (Wen 1978; Huang et al. 1985; Zhou 1998), matched with the primitive features of hominid fossil from the same site.

The features of the Yuanmou hominid have not been debated much; however, age determination has been controversial over the past decades. The paleomagnetic dating for hominid incisor-bearing layer gave the following results: 1.7 Ma (Li et al. 1976), 0.7 Ma (Hyodo et al. 2002), and 1.7 Ma (Zhu et al. 2008); the ESR dating result is 1.1–1.6 Ma (Huang and Grün 1998); the analysis of comprehensive lithostratigraphy, biostratigraphy, magnetostratigraphy result and support age of middle Pleistocene is probably 0.5–0.6 Ma (Liu and Ding 1983). An early Pleistocene age (1.7 Ma) is widely accepted.

Homo erectus yuanmouensis is the earliest hominid fossil to date in China; however, the incisors and tibia could not provide much morphological traits for such species. Southern Yuanmou Basin has thick Plio-Pleistocene fluviolacustrine deposits, which have great potential for finding more hominid and culture remains. Unfortunately, just two excavations have been conducted in the past half century. Further field survey and excavation is necessary for future projects.

Basic Biographical Information

Georges Zbyszewski (1909–1999) (Fig. 1) was born in Russia, son of a Russian countess and a Polish military officer. During the Russian Revolution, he moved with his family to Paris, where several years later he adopted French nationality and graduated in Natural Sciences at Sorbonne University, becoming an assistant of Jacques Boucart (1891–1965). In France, he met several Portuguese researchers such as the geologist Carlos Teixeira (1910–1982) and the geographers António de Medeiros Gouveia (1900–1972) and Orlando Ribeiro (1911–1997).

In 1935, Georges Zbyszewski moved to Portugal, advised by Jacques Boucart, in order to study the Quaternary lands from the Portuguese coast, with the idea of elaborating his Ph.D. dissertation. The aim of Zbyszewski's studies was to compare the Portuguese Quaternary formations with those from the north of Morocco, which had been studied before by Boucart. George Zbyszewski worked then with António de Medeiros Gouveia, which was preparing his Ph.D. dissertation about the Algarve region. Zbyszewski finally established in Portugal in 1940 invited by António Viana, Chief of Serviços Geológicos de Portugal (Geological Services of Portugal), to work in that institution. He crossed the country, elaborating studies and making important discoveries regarding paleontology (Fig. 3), geology, and archaeology, publishing several scientific articles regarding these disciplines.

In 1973, he started to teach in the Faculty of Sciences of Lisbon University.

Georges Zbyszewski also contributed to the elaboration of geological charts, working in Serviços Geológicos de Portugal till 1979, when he retired.

Major Accomplishments

Georges Zbyszewski was a great contributor to the advancement of Portuguese geology, paleontology, and archaeology. In terms of his scientific achievements, Georges Zbyszewski was the author of 281 publications, 54 of which were about paleontology. He published 105 studies on the Portuguese Quaternary (research about

prehistoric fauna and lithic industries), covering the entire Portuguese territory. Concerning geology, he published 96 works and also 26 articles about other several subjects. He was the author or co-author of 45 geological charts of Portugal, in the scale of 1/50,000 and the respective explicative information.

Zbyszewski's studies about the Quaternary led him to publish, besides particular notes, valuable synthetic works on this subject, such as *Le Quaternaire du Portugal* (Fig. 2) and *A classificação do Paleolítico antigo e a cronologia do Quaternário de Portugal* (1942). The studies carried out in the region of Alpiarça (1946) were a decisive contribute for the knowledge of the Quaternary lands, in which he studied not only the characteristics of the terraces of the Tagus in this region but also the Paleolithic industries related with these deposits.

The presence of Henri Breuil in Portugal during World War II allowed a close collaboration with Zbyszewski. Several publications came out from this partnership such as "Contribuição para o estudo das indústrias paleolíticas de Portugal e sua relação com a Geologia do Quaternário" (1942), whose first volume constituted the *XXIII Comunicações dos Serviços Geológicos*, dedicated to the study of the main quarries from both sides of the ancient Tagus estuary, and the second volume, published on *XXVI Comunicações dos Serviços Geológicos*, dedicated to the quaternary

beaches in the Estremadura coastline and the fluvial terraces of the Low Tagus Valley (1945).

Still regarding prehistoric archaeology, Zbyszewski studied the remains found in caves and rock-shelters that he surveyed or in which survey he collaborated. Some examples are the Almonda's caves (1941 and 1947); Lapa da Bugalheira (1941); Lapa da Maceira, Vimeiro (1949); and the caves of Ponte da Lage (Oeiras) (1957), of Salemas (Ponte de Lousa) (1962), of Columbeira (Bombarral) (1963), and of Alcobertas (1971) and Lapa do Bugio in the same year. He was dedicated also to the study of Late Prehistory in Portugal, conducting research about the hypogea of Casal do Pardo (Palmela), the Tholoi of Praia das Maçãs (1961) and of Calhariz (Sesimbra), and the dolmen of Casal do Penedo (1951), of Casainhos, and of Várzea de Sintra (1977).

Zbyszewski participated in countless conferences and scientific meetings, being since 1956 the permanent representative of Geological

Zbyszewski, Georges, Fig. 3 Bones (femur and tibia) of ancient Paleoloxodon found by Zbyzewsky associated with lithic artifacts

Services of Portugal in the Stratigraphy Commission of the International Conference of Geology. He was a member of several scientific societies from Portugal and other countries, for example, the French Geological Society, French Prehistoric Society, and Portuguese Association of Archaeologists, among others (Mota, n. d.).

The recognition of his work granted him the title of *Chevalier des Palmes Académiques* (Knight of the Academic Palms) (1959) and *Chevalier de l'Ordre National du Mérite* (Knight of the National Order of Merit) (1969), both attributed by the French State.

In 2005, the name of Georges Zbyszewski was given to one of the streets from Lisbon.

Zeuner, Frederick Everard

David R. Harris
Institute of Archaeology, University College London, London, UK

Basic Biographical Information

Frederick Zeuner (Fig. 1) was an intellectually brilliant and innovative natural scientist who founded the subdiscipline of environmental archaeology.

Born in Berlin in 1905, Zeuner was educated at the universities of Berlin, Tübingen, and Breslau (now Wroclaw in Poland) where he studied

Zeuner, Frederick Everard, Fig. 1 Frederick Zeuner, *c.* 1955. (Reproduced by permission of the Institute of Archaeology, University College London)

paleontology and geology with mineralogy, geography, zoology, and botany as minor subjects. At Breslau he studied under Walther Soergal, whose research on Quaternary glaciations and mammalian faunas influenced Zeuner and who supervised his Ph.D. (1927) on uplifted river terraces southwest of Breslau. At age 20, he was appointed *Assistent* and later *Privatdozent* in the Breslau Institute of Geology and Palaeontology. He qualified as a university teacher in 1931 with a thesis on Tertiary insects and was appointed to a lectureship at the University of Freiburg-im-Breisgau.

By 1934 Zeuner had already published over 30 scientific papers and monographs, but his career was then disrupted by the political turmoil in Germany where the Nazis had gained power in 1933. His Jewish wife was classified as a "non-Aryan" and Zeuner was dismissed from his university post. The couple left Germany for London in 1934 where, as an academic refugee, Zeuner was supported by the Academic Assistance Council (later the Council for Assisting Refugee Academics or CARA) which Sir William Beveridge, Director of the London School of Economics, and other prominent academics had established in May 1933. Already known for his many publications on fossil insects, Zeuner became a Research Associate in Palaeontology at the British Museum (Natural History) and in 1939 published a major monograph, *Fossil Orthoptera Ensifera*, for which he was awarded a London University D.Sc. degree. Although formally classified as an enemy alien, he succeeded in becoming a naturalized British citizen, and during the Second World War he joined the Anti-Locust Research Centre at the Museum. At this time he completed his first two books (see below) and began publishing papers on prehistoric archaeology and Pleistocene mammals.

Soon after his arrival in London, circumstances arose that changed the direction of Zeuner's scientific career. Through the determined efforts of Mortimer Wheeler, the then Director of the London Museum, and his wife Tessa, the Institute of Archaeology was founded, without premises in 1934 and formally in 1937 in a refurbished mansion, St. John's Lodge in Regent's Park (Evans 1987: 1–18). Wheeler's vision of archaeology included training in natural sciences, and, with further support from CARA, Zeuner joined the Institute as an Honorary Lecturer in Geochronology in 1936 – an event that marks the beginning of what was to become the subdiscipline of environmental archaeology. Teaching at the Institute was suspended during the Second World War, but although his fieldwork was curtailed, Zeuner continued to publish paleontological, geological, and archaeological papers. In 1944 the University of London agreed, in light of his exceptional qualifications, that he should be promoted to a (part-time) professorship, and in 1946, the same year that Gordon Childe became Director of the Institute (Fig. 2), he became the world's first Professor of Environmental Archaeology (Harris 2009: 130). His appointment later became full time and he continued to teach at the Institute and undertook fieldwork throughout the world until his premature death at the age of 58 in November 1963.

Zeuner, Frederick Everard, Fig. 2 Zeuner (*left*) with Professor Gordon Childe, date and location not recorded, possibly in Regent's Park. (Reproduced by permission of the Institute of Archaeology, University College London)

Major Accomplishments

The defining achievement of Zeuner's career was his ability to master evidence from across the natural sciences to examine, on a world scale, the sequence of environmental changes that occurred in the Quaternary and relate them to prehistoric archaeology and mammalian faunas. His talent for comparative field observation, his command of the multilingual European scientific literature, and his ability to synthesize a wide array of data were reflected in his first book, *The Pleistocene Period* (1945). In it he sought to establish an absolute chronology by relating changes in climate and sea level to evidence from fluctuations in solar radiation (following the Serbian mathematician Milutin Milankovitch's astronomical calculations, Gribbin 2002: 476–80), glacial moraines, loess (wind-blown silt from glacial sediments), river terraces, ancient shore lines, cave deposits, and changes in fauna. Then, in a companion volume *Dating the Past* (1946), which drew on lectures Zeuner gave at the Institute of Archaeology, he introduced the new subject of geochronology, described its techniques, comprehensively examined the relationship of Pleistocene (ice age) and Holocene (postglacial) environmental changes worldwide to archaeological periods, principally the Paleolithic, and concluded with a section on dating the prehuman past of the Earth.

These two publications established Zeuner's international reputation as a leading environmental scientist, but preceded the demonstration in 1950 by Willard Libby and his colleagues at Chicago that organic materials could be directly dated by the radiocarbon technique. Zeuner responded to this breakthrough by immediately setting up his own radiocarbon dating project in London and produced a series of results, including dating the Neolithic occupation of Jericho excavated by Kathleen Kenyon (Harris 2009: 130–31, 139: Notes 5 and 6).

Through the 1950s and early 1960s, Zeuner undertook field projects in many parts of the world and published a multitude of archaeological, geological, and faunal papers. In his last decade he worked increasingly on animal domestication. This culminated, just before his premature death, in the publication of his magnum opus, *A History of Domesticated Animals* (1963), in which he presented domestication in its widest sense as more a biological than a cultural process. Zeuner was a lucid and fluent lecturer and at the

Institute of Archaeology, he inspired and trained a succession of research students, many of whom went on to develop the subdiscipline of environmental archaeology that he created.

Zhan, Guo

Zev Cossin
Department of Anthropology, University of Illinois at Urbana-Champaign, Urbana, IL, USA

Basic Biographical Information

Dr. Zhan received his M.A. in Mongolian History and Yuan Dynasty History from the Chinese Academy of Social Sciences and studied at the Archaeology Department of Peking University. Guo Zhan is the director of the World Heritage Expert Committee of China, a nongovernmental professional consultant institution designated by the State Administration of Cultural Heritage (SACH) as well as a senior researcher on history and archaeology and concurrent professor at the Chinese Academy of Governance. Dr. Zhan is the ICOMOS vice president and was first elected by the 15th General Assembly in 2005. He also is the vice-chairman and secretary-general of ICOMOS-China as well as director of IICC-Xi'an.

Major Accomplishments

Dr. Zhan took part in the deliberations and research with regard to the Nara Document on Authenticity in Nara, Japan, in 1994 and 2004.

He has worked within the State Administration of Cultural Heritage on the protection, management, and research of ancient architecture, historic cities, and archaeological sites, successively acting as project manager, deputy division chief, director of the General Office, director of the Cultural Relics Division, director of the Division of World Heritage, and commissioner of the Department of Cultural Heritage Protection until his retirement.

Most recently, Zhan has organized the ICOMOS Asia-Pacific Group meetings in China, worked with the international and national post-disaster heritage rescue and protection measures in the wake of Wenchuan earthquake in 2008, and presented at various symposia on the protection and management of cultural landscapes, industrial heritage, and the Grand Canal of China.

He is engaged in the conservation and monitoring of heritage sites in China and serves as chair of the International Symposium on the Concepts and Practices of Conservation and Restoration of Historic Buildings in East Asia. He participated in the revision of the *Principles for the Conservation of Heritage Sites in China* and organized the translation into Chinese of *History of Architectural Conservation* written by Jukka Jokilehto, the *ICOMOS Charter on the Interpretation and*

Presentation of Cultural Heritage Sites (ICIP), *Preparing World Heritage Nominations* (World Heritage Centre, ICOMOS, IUCN), and of some interesting discussion papers of ICOMOS International Scientific Committee on the Theory and Philosophy of Conservation and Restoration.

Zheng Dekun

Raphael Wong
University of Oxford, Oxford, UK

Basic Biographical Information

Cheng Te-K'un 鄭德坤 (Zheng Dekun) (1907–2001) was born in Xiamen, Fujian Province, China, in 1907 (Cheng 1981; An interview with Professor Cheng Te-K'un 1985; Cheng 1994b; Cheng Te-K'un jiaoshou jianli 1994a; Deng 2000 and 2017). He attended the Yenching University in Beijing in 1926. Though beginning university as a premedical student, he completed a bachelor's and a master's degree in Chinese literature. Upon graduation, Cheng joined the Harvard–Yenching Institute as a research fellow and conducted research on the Chinese classics *Classic of Mountains and Seas* (Shanhaijing 山海經) and *Commentary on the Water Classic* (Shuijingzhu 水經注). He visited historical sites across China with Professor Gu Jiegang 顧頡剛 (1893–1980). His monograph, *A Brief History of the Chinese Mortuary Objects* (Zhongguo mingqi 中國明器), and coauthored with Shen Weijun 沈維鈞, was published in the first volume of the *Harvard–Yenching Institute Monograph Series* and used as a teaching material at Waseda University in Japan.

In 1933, Cheng became a professor at Amoy University (modern Xiamen University) in Fujian. He established the university's Museum of Chinese Cultures, which has now developed into the Museum of Anthropology. He also led the first excavation in the province, bringing to light four Tang dynasty tombs at Quanzhou. At the request of the Harvard–Yenching Institute, he started teaching Chinese history at the West China Union University (now Sichuan University) in Chengdu, Sichuan, in 1936, where he also served as curator of the university's museum. In 1938, Cheng embarked upon a doctorate in archaeology at Harvard University and completed a thesis on the prehistory of Sichuan. Upon graduation, he returned to his position at the West China Union University where he reorganized the museum collection and advocated for the use of "native materials" in teaching. He also became editor for *Journal of the West China Border Research Society* (Hauxi bianjiang yanjiu xuehui zazhi 華西邊疆研究學會雜誌).

Cheng's work brought his name to the attention of the British Council. He was invited to give lectures at the universities of Oxford, Cambridge, and London and elected a fellow of the Royal Anthropological Institute of Great Britain and Ireland in 1947. After staying in Hong Kong for 3 years, Cheng was invited back to Cambridge as the lecturer in Far Eastern Art and Archaeology in 1951. During his time in Cambridge, he published his monograph *Archaeological Studies in Szechwan* and devoted himself to the writing of the series *Archaeology in China*. Cheng was invited to lecture at Princeton University in America, the

University of Malaya in Malaysia, and Nanyang University (now National University of Singapore). He organized excavations in Malaysia, resulting in the publication of *Archaeology in Sarawak*. Cheng was awarded an honorific plaque by the board of the Museum of Far Eastern Antiquities in Stockholm in 1963 and honored as emeritus reader in Chinese archaeology and emeritus fellow of Wolfson College, Cambridge, when he retired in 1974.

Cheng was soon invited to join the Chinese University of Hong Kong. He was appointed the dean of the faculty of arts and pro-vice-chancellor in academic affairs. He retired in 1979 but continued to serve as emeritus professor of the department of fine arts, as well as honorary director of the Center for Chinese Archaeology and Art and the Institute of Chinese Studies. He was awarded an honorary degree in literature by the Chinese University in 1981 and elected as a corresponding fellow of the British Academy in 1985.

Major Accomplishments

Cheng's work on Sichuanese archaeology has earned him the title of "Father of Sichuanese Archaeology," granted to him by Japanese archaeologist Seiichi Mizuno (1905–1971) (An interview with Professor Cheng Te-K'un 1985). His monograph on Sichuan was the first publication in a Western language that provided an overall survey of materials from the province, and, thus, drew attention to a long-overlooked area. In particular, the chronological framework proposed for prehistoric Sichuan is considered by scholars to be most valuable. The three-volume *Archaeology in China* drew on newly discovered archaeological materials and provided a comprehensive survey of China in prehistory, Shang, and Zhou periods. The series, later translated into Japanese, has been praised for linking Chinese archaeological activity to world knowledge, at a time when English references on Chinese archaeology was limited. Cheng also published extensively on Chinese jades, ceramics, and paintings.

Cheng is also known for having laid a foundation for the development of archaeology in Hong Kong. He founded, and became director of, the Centre for Chinese Archaeology and Art under the Institute of Chinese Studies at the Chinese University. He invited archaeologist Lin Shouchin 林壽晉 (1929–1988) to join the history department, who was one of the first few scholars from the Chinese Academy of Sciences to teach in Hong Kong (Deng 2000). To this day, the Chinese University remains at the forefront of the study of Chinese art and archaeology in the region. Professor Cheng also served as member of the Antiquities Advisory Board of Hong Kong and a consultant of the ancient book publishing planning team under the People's Republic of China's State Council.

Zhoukoudian, Archaeology of

Xiaoling Zhang[1] and Chen Shen[2]
[1]Department of Palaeoanthropology, Institute of Vertebrate Paleontology and Paleoanthropology, Chinese Academy of Sciences, Beijing, China
[2]Department of World Cultures, Royal Ontario Museum, Toronto, ON, Canada

Introduction

Zhoukoudian is located in the Fangshan District, 55 km southwest of downtown Beijing. A hill called Longgushan "Dragon Bone Hill" was known by local farmers in the early twentieth century for Ordovician limestone quarrying. Zhoukoudian was first visited by the Swedish geologist Johan Gunnar Andersson as a potential location of quaternary mammalian fossils in 1918. The American paleontologist Walter Granger later identified fossils at the Dragon Bone Hill in 1921. Austrian paleontologist Otto Zdansky then discovered two *Homo erectus* teeth from the Locality 1 cave in 1926, the same year Canadian anthropologist Davidson Black named the hominid teeth as a new species *Sinanthropus pekinensis* (Black 1927). Black secured funding from the Rockefeller Foundation and started the official international collaboration with the Cenozoic Research Laboratory (today's Institute of Vertebrate Palaeontology and Palaeoanthropology, Chinese Academy of Sciences) in 1927. Both Davidson Black and Chinese paleontologist Yang Zhongjian led excavations at the site, where the first skull of Peking man was recovered by Chinese anthropologist Pei Wenzhong in 1929. Since 1930, Zhoukoudian has become one of the most important paleoanthropology sites for the study of human evolution in the world.

Definition

Zhoukoudian (aka Choukoutien in early publications) is a UNESCO world heritage site in China. It refers to a village whose landscape includes 27 localities of hominids, fauna, and cultural remains. Four of these localities yielded significant hominid fossils of different species. Locality 1 cave (Peking man site) unearthed 203*Homo* fossil fragments of *Homo erectus*, belonging to more than 40 individuals (Fig. 1). These included six nearly complete skulls, five of which were lost during WWII. The Peking man skulls are the most important study subjects for Asian *Homo erectus* and have been published extensively. A human premolar unearthed from Locality 4 in 1973 was unknown to the world, which probably belongs to Asian Archaic *Homo sapiens*. Locality 26 (aka the Upper Cave) yielded 10 individual fossil remains belonging to modern human *Homo sapiens sapiens*, which are also well-studied specimens in paleoanthropology. The latest discovery of human fossils at Zhoukoudian was from the

Zhoukoudian, Archaeology of, Fig. 1 The only surviving Peking man skull, examined by one of the authors (Dr. Chen Shen) at the Institute of Vertebrate and Paleontology and Paleoanthropology in 2010. (Photo credit, author (ZXL))

Tianyuan Cave where 34 fragments were found, including a mandible, teeth, and postcranial bones, which present a nearly complete individual (Shang and Trinkaus 2010). Direct AMS 14 C dating from a limb fragment produced the most reliable and earliest date for China's Homo sapiens sapiens at Zhoukoudian, ranging from 42,000 to 38,500 years ago. In addition, six localities (Locality 1, 4, 13, 15, 22, and 26) yielded a large assemblage of lithic artifacts and other cultural relics such as fire remains and ornaments.

Key Issues/Current Debates/Future Directions/Examples

Locality 1 (Peking Man Site)

The most focused studies at Zhoukoudian have been dating, climatic context, lithic technology, and hominid and carnivore remains of the cave. Recent dating studies have changed the old perspectives about when Peking man lived, suggesting the hominid appeared at Zhoukoudian as early as 780,000 years ago (Shen et al. 2009), when the world was in extreme cold and dry climate. With cultural material deposits measuring 40 m deep, it is possible to show the occupation of early hominids may have lasted half a million years at Zhoukoudian. Lithic artifacts were recovered from deposits of three cultural phases (early layers 8–10, middle layers 6–7 and QII, and late layers 3–5), accounting for more than 17,000. These were catalogued into ten classes with 40 types of stone tools, which suggest a gradual transition from simple use to a more complicated tool manufacturing process at the site.

Locality 15

The lithic artifacts from Locality 15 (dated to the late Middle Pleistocene and early Late Pleistocene Periods) reveal evidence suggesting that lithic technology at the site was more developed than that of their predecessors at the Locality 1 (Gao 2000). The Zhoukoudian Locality 15 hominid (most likely East Asian *Homo heidelbergensis* although no fossil found yet) effectively mastered sophisticated core reduction modes, represented by multi-directional flaking and alternate flaking, which were not evident at the Locality 1.

Fire Use

One of the issues debated about Zhoukoudian's cultural contents is the use of fire. Although there is no structurally defined hearth at the Locality 1 site, burnt ashes, charcoals, burnt bones, and even stone tools were often identified in situ. Whether or not these fire-related activities were the result of intentional human control and manipulation or of natural causes and hydratic force is the subject of further studies. Since 2009, full-

Zhoukoudian, Archaeology of, Fig. 2 Ongoing excavation at Zhoukoudian Locality 1 by scientists from Chinese Academy of Sciences since 2009. (Photo credit: the author (SC))

scale excavations at the Locality 1 have been carried out by Chinese scientists and have revealed possible fire floors at the layer 4 (Fig. 2). An interdisciplinary research team is taking samples for all relevant scientific laboratory testings, and hopefully the results will advance our knowledge about the human use of fire in the Middle Pleistocene at Zhoukoudian.

Hunters or Hunted

Since 1980s, a number of studies related to Peking man behaviors have challenged old thoughts suggesting that Locality 1 was primarily a den of the giant hyena. Lewis Binford argued the deposition of fossil remains were likely the results of carnivores' activities (Binford and Ho 1985). Later Steve Weiner (Weiner et al. 1998) and Paul Goldberg (Goldberg et al. 2001) cautioned early reported evidences of fire use and proposed the fire-ash and burned bones at the cave probably were natural process of the formations. A study by Noel Boaz (Boaz et al. 2004) on spatial distribution of hominid fossils further dismissed the idea that the Zhoukoudian Locality 1 cave was a home base for Peking man. Instead, the cave was more likely used by carnivores scavenging the Peking man. The 20 years of studies in favor of carnivore activities over hominids were all based on analyses of limited samples of fauna and sediment.

Concerning all the discoveries and debates, new systematic excavations and multi-disciplinary research will bring the solutions. The comprehensive study of lithics including both technology and function will reveal the behavioral capability. Further taphonomic and zoo-archaeological research, physical anthropology, chronology dating, and paleoenvironmental study should be all involved.

Zhoukoudian: Geography and Culture

Liu Yang
Laboratory of Human Evolution, Institute of Vertebrate Paleontology and Paleoanthropology, Chinese Academy of Sciences, Beijing, China
University of Chinese Academy of Sciences, Beijing, China

Introduction

The Zhoukoudian site (39°41′N, 115°51′E) is a series of cavities on the Dragon Hill, which is located at Zhoukoudian, Fangshan District, about 50 km southwest of Beijing at an elevation of about 128 m above sea level (Fig. 1). So far at least 27 fossil localities have been systematically studied and numbered. These are known not only for the discoveries of human remains but also for the long sequence of lithic and animal bone assemblages produced through several excavations in the various localities. Among all the localities, the Locality 1, situated on the northern slope of Dragon Bone Hill, including the "Peking Man Cave" and the Pigeon Hall, in which several human skeletal remains were first discovered in 1929 and named collectively as "Peking Man", is the most important one. At the time, the impact of finding the human fossils, originally called *Sinanthropus*, was immense. Continued excavations at Locality 1 uncovered an additional series of human fossils derived from a thick, well-stratified sequence.

Definition

The fossiliferous potential of the Zhoukoudian area was first investigated by geologist J. Gunnar Andersson in 1919 (Andersson 1919) at Chicken Bone Hill which now termed Zhoukoudian Locality 6. The main cave infilling, a hill of Ordovician limestone named Dragon Bone Hill, was discovered by J. Gunnar Andersson, Otto Zdansky, and Walter Granger in 1921 (Andersson 1922). Long-term fieldwork was undertaken from 1921 to 1937, and many important discoveries were recovered in the Dragon Bone Hill, especially at Locality 1. The first excavation was undertaken by Zdansky in 1921 and 1923, and three isolated hominid teeth were recovered (Black 1926; Zdansky 1927; Weidenreich 1937). Five complete *Homo erectus* skulls and a number of mandibular and dental remains were discovered from 1929 to 1936. The first identified and also the well-preserved recovery skull (skulls E), discovered in 1929 by Pei Wenzhong (Pei 1930; Black 1931; Black et al. 1933), was a turning point in the investigation of the site and helped to ensure continued funding (Cormack 2000). Hominid discoveries were made each field season, but the excavation of skulls LI, LII, and LIII during 11 days in November 1936 by Jia Lanpo was particularly noteworthy (Jia 1999). The sixth complete skull was discovered during fieldwork from the 1950s to 1970s. The inventory of all of the Peking Man fossils from Locality 1 is as follows: 6 complete or nearly complete skulls, 12 large skull fragments, 15 incomplete mandibles, 157 teeth, 3 humerus fragments, 1 clavicle, 7 femur fragments, 1 tibia fragment, and a lunate

Zhoukoudian: Geography and Culture, Fig. 1 A map showing the position of the Zhoukoudian site (After Andersson 1943)

bone. The specimens represent materials from more than 40 male and female individuals of different ages. The Peking Man cave is the richest *Homo erectus* site in the world and marked a new era in our understanding of the history of human evolution.

Zhoukoudian is known not only for the discoveries of human remains but also for the long sequence of lithic and animal bone assemblages obtained at several excavations in the various localities (Jia and Huang 1990). Over 100,000 pieces of stone artifacts have been unearthed from Locality 1 alone (Fig. 2). The variety of raw materials used to make the stone artifacts include quartz, flint, sandstone, etc.; local quartz is dominant and outcrops exposed by weathering processes from such places as the riverbed and the hill slopes in the vicinity of the cave. The most striking feature of the Peking Man industry lies in use of the direct bipolar percussion technique, which was created by Peking Man himself principally because of the scarcity of better quality material in the region. The stone tools include scrapers, points, choppers, burins, borers, and so on, using different production techniques. Changes in tool size, raw materials used and the flake-producing techniques over time demonstrate that the lithic technology of Peking Man progressively evolved.

Nearly 100 species of mammalian fossils have been found in Locality 1, including thick-jaw deer (*Megaloceros pachyosteus*), sika deer (*Cervus grayi*), gazelle (*Gazella*), saber-toothed tiger (*Machairodus*), striped hyena (*Pachycrocuta sinensis*), and cave bear (*Ursus spelaeus*), among others. Some of these were clearly part of the diet of Peking Man.

Several ash layers are interspersed relatively widely within the 40 m of deposits. More strikingly, ash residue in the fourth layer was quite thick, and the thickest part is over 6 m. In these ash layers, there were large quantities of burnt stones, charred bones, and burnt seeds of hackberries. The analysis of black layer samples and associated charred bone fragments confirms the existence of remains of fire use by Peking Man.

The Peking Man cave sediments, more than 40 m thick, have been divided from bottom to

Zhoukoudian: Geography and Culture, Fig. 2 The stone artifacts from Zhoukoudian, Locality 1 (After Pei and Zhang 1985)

top into 17 layers (Fig. 3). Human remains were found in nearly all layers (1–10) (Pei and Zhang 1985). The lithic assemblages were concentrated in several horizons (layers 1, 3, 4, top of 8 and 10), and some artifacts were found scattered throughout the thick brecciated layers (layers 5–9). The sediments also record much information regarding paleoclimatic change (Yang et al. 1985). They are characterized by breccias layers interbedded with non-breccia layers. The breccia layers imply a cold climate and the non-breccia layers imply a warm climate. There are many sedimentary cycles composed of subdivided beds in each layer, which may reflect paleoclimatic variations of different scales (Liu 1985).

The geological age of the deposits of Locality 1 is Middle Pleistocene based on the mammalian assemblages from the cave. A series of detailed geological, palynological, and paleontological studies, as well as dating, has contributed significantly to our understanding of the complex stratigraphy and the dates of the Peking Man site. Early attempts to date Locality 1 may be traced to 230Th/234 U ages measured on two fossil bones by Cherdyntsev (1971). In the late 1970s, numerical dating was carried out at several Chinese institutions using different techniques, including U-series disequilibrium (Zhao et al. 1985a), fission track (Liu et al. 1985), paleomagnetism (Qian et al. 1985), thermoluminescence (Pei 1985), and amino acid racemization (Zhou 1989). As a result, the following chronological sequence has been proposed (Zhao et al. 1985b): c. 700 ka for the lowest fossiliferous horizon (layer 13), based mainly on paleomagnetic stratigraphy; c. 500 ka for the lowest stone artifact-containing layer (layer 10), based on fission track dating of sphene grains extracted from ash deposits; and c. 230 ka for the uppermost strata (layers 1–3) based on 230Th/234 U dating of fossils. Alongside technical advances in dating methods, chronological studies of Locality 1 have continued, but the newer age results do not significantly alter the generally accepted temporal framework, which places the age of the hominid remains in the range of about 230–500 ka. At present, a new result which was made by a new radiometric method indicates that the date of the oldest human fossils is about 770,000 years ago and that *H. erectus* at Zhoukoudian lived during a relatively mild glacial period (Shen et al. 2009).

Zhoukoudian: Geography and Culture, Fig. 3 A sketch showing the deposits (West Profile) of ZKD Locality 1 and the stratigraphic positions of the cranial discoveries (From Wu et al. 2011)

Key Issues/Current Debates/Future Directions/Examples

There are some hot topics on which many subsequent studies have focused. The first is dating. Although many dating methods have been used to determine the age of Locality 1 and a general temporal framework has been obtained, the validity of the assumptions used in the dating and the accuracy of the derived ages remain problematic. Even the latest result which was made by Shen et al. (2009) has been subject to debate. The second is the use of fire. There is no doubt that the ash layers existed; even the ash residue in the fourth layer was quite thick. Furthermore, abundant burnt stones, charred bones, and burnt seeds of hackberries were found. Some

of these samples have been analyzed and confirm the existence of remains of fire used by Peking Man (Wu 1999), but also there are some contradictions (Weiner et al., 1998). The third concerns the function of the cave: whether or not the cave was Peking Man's home. Because of the long sequence of the sediments, as well as other evidence, Peking Man was considered to have lived long term in the cave. But Binford (Binford and Ho 1985) thought the cave was a trap. The fourth focuses on the lithic industry. From the view of geology, the Zhoukoudian industry is old, but the small elongated flakes produced by the bipolar method are even Upper Paleolithic products in the West (Teilhard and Pei 1932). Finally, the issue of whether this hominid species was a direct ancestor of later eastern Asian populations or a side branch in human evolution impacts on the two principal current hypotheses about the origin of modern *H. sapiens* (e.g., Wolpoff et al. 1984).

Zimbabwe: Cultural Heritage Management

Simon Makuvaza
Faculty of the Built Environment, National University of Science and Technology, Bulawayo, Zimbabwe

Introduction

Zimbabwe has a history of formal cultural heritage management which dates back to the colonial period. The country was a British colony from 1890 and named Rhodesia after Cecil John Rhodes. It won independence in 1980 after a war of liberation. The management of cultural heritage has remained conservative, lagging behind modern management practices. In Zimbabwe, cultural heritage is defined by law and includes some of the following: any historical building, ruin, statue, grave, cave, rockshelter, and area of archaeological or historical interest. This entry discusses the history of cultural heritage management in Zimbabwe and the challenges that have often been encountered when managing it. Finally, it looks at some of the concerns that have been raised about cultural heritage in Zimbabwe and how its management should be improved.

Historical Background

When the colonial government introduced formal cultural heritage management in Zimbabwe, it had assumed that there was no cultural heritage protection in the country. Prior to that time, however, cultural heritage was protected by traditional methods and laws, which were upheld by the local communities and enforced by traditional leaders. These traditional laws were not written down, and they constituted what is now known as customary laws (Chiwaura 2005). The introduction of formal laws to manage cultural heritage was part of efforts to protect the dry-stone ruins of Great Zimbabwe, Khami, Dhlodhlo (Danang'ombe), Zinjanja (Regina), Nalatale, and others (Fig. 1), which early European settlers had incorrectly believed were storage rooms for gold and other precious minerals for King Solomon and the Queen of Sheba (Mahachi and Ndoro 1997).

To protect these sites from pillaging and destruction, the Legislative Assembly enacted the Ancient Monuments Protection Ordinance in 1902. This was followed by the 1912 Bushman and Relics Ordinance aimed at protecting rock art. The promulgation of this ordinance emanated from the concern that the rampant pillaging of rock art by early European settlers in South Africa would spread into Rhodesia (Ndoro 2001). Both the 1902 and the 1912 ordinances were later repealed and replaced by the comprehensive Natural Historical Monuments and Relics Act of 1936. A wide range of cultural and natural heritage sites were for the first time protected and managed under this act. Following its enactment, the Commission for the Preservation of Natural

Zimbabwe: Cultural Heritage Management, Fig. 1 Part of Southern Africa showing some of the archaeological cultural heritage sites in Zimbabwe

and Historical Monuments and Relics, commonly known as the Commission, was established to implement the protective legislation. Its objective was to coordinate activities related to the preservation of ancient, historical, and natural monuments, relics, and other objects of aesthetic, historical, archaeological, or scientific interest. The Act was later repealed and replaced with a new Act, CAP 313, after the Commission and the National Museums of Rhodesia were amalgamated in 1972 to establish the National Museums and Monuments of Rhodesia. Ndoro (2001) viewed this amalgamation as a positive development as it ensured that all cultural heritage property had to come under a single administration. However, Chipunza (2005) saw the merger differently, contending that the activities of the Commission to protect cultural heritage sites became limited as the inspection of monuments was no longer recognized as a profession. The new organization was divided into five administrative regions and headquartered first in Harare, then Salisbury, and placed under the ministry of Internal Affairs. Open-ended contracts for White regional and executive directors were established, probably to safeguard the interests of the White community. The problem of open-ended contracts is that cultural heritage continues to be administered with the same management style without any chance for change or improvement. At independence, the heritage agency's name was changed to the National Museums and Monuments of Zimbabwe (NMMZ) and administered under the ministry of Home Affairs. Although there are opposing views regarding the joining of the two organizations, the objective of the new

body did not differ much from that of the Commission, except in few instances where it provides for the establishment of museums and the board of trustees. The protection of cultural heritage remained under this law and administration until independence, when it was adopted wholesale by the NMMZ.

Key Issues/Current Debates

Management Prior to Independence

Soon after its establishment, the Commission began to compile a list of rock paintings, ruins, and places of scenic beauty. A monuments register was created, with 2,400 sites initially entered. By 1954, the Commission had proclaimed 79 of these sites as national monuments (Summers and Cooke 1959). A number of sites declared as national monuments were related to colonialism, perhaps as part of legitimizing this cultural heritage in a country where Black people were the majority. Activities such as archaeological excavations, alteration, defacing or removal, and export of an ancient monument or relic were not permitted without the written consent of the Commission. Separate registers for historical buildings were also subsequently prepared in each of the country's major cities, and although they were protected by law, not many were declared as national monuments. Historical Buildings Advisory Committees were also established to provide advice on how they were to be protected and managed.

A major challenge during the formative years of the Commission was the lack of staff and equipment to carry out maintenance work on proclaimed monuments and other sites. Following an agreement with the National Parks Advisory Board in 1951, Victoria Falls and the Zimbabwe Ruins (Great Zimbabwe) were temporarily transferred to the Parks Board for management. Additional monuments were transferred to the Parks authorities after a further agreement was made in 1961. Table 1 shows a list of monuments that were transferred and were to be managed by the Parks Board, while Table 2 shows monuments that were to be co-managed by the two organizations.

Zimbabwe: Cultural Heritage Management, Table 1 Monuments handed over to the Parks Board in 1951 for management

Registered number	Name of monument
1	Victoria Falls Reserve
4	World's View Hill-Matopos
9	Sinoa (Chinhoyi) Caves
10	Rhodes-Inyanga Estate
12	Pungwe Falls
29	World's View Farm-Nyanga
35	Chirinda Forest
42	Mtoa Ruins-Hwange
44	Mjelele Valley Road Cave
46	Ewanrigg Aloe Garden
51	Rupisi Hot Springs

Zimbabwe: Cultural Heritage Management, Table 2 Monuments that were to be co-managed by the Commission and the Parks Board

Registered number	Name of monument
2	Zimbabwe Ruins
7	Bambata Cave
8	Nswatugi Cave
19	Silozwane Cave
20	Gulubahwe Cave

The hope of the Commission was that these monuments were to be transferred back in future when adequate staff members were employed and equipment acquired. Only Great Zimbabwe and a few other sites were returned in 1975, but the rest including the Victoria Falls remained under the current Zimbabwe Parks and Wildlife Management Authority. Attempts to take over the management of Victoria Falls by the NMMZ in recent years from the Parks authorities have caused a considerable dispute between the two organizations (Makuvaza 2010).

Many sites that were proclaimed as national monuments were then fenced, and brass plaques were erected to advise the public that they were now government property and protected by law, and breaking the law was by order liable to prosecution (Fig. 2). Proclamation of sites as national monuments, fencing and phraseology on the plaques instantaneously sidelined local communities from managing their cultural heritage in fear of being prosecuted.

Zimbabwe: Cultural Heritage Management, Fig. 2 Plaques erected at cultural heritage sites proclaimed as national monuments to warn the public that they were protected by law

Zimbabwe: Cultural Heritage Management, Fig. 3 Brass plaques erected at cultural heritage sites after the enactment of the Act, CAP 313

Local communities had also begun to be isolated from managing cultural heritage as they were evicted from their original areas to create European settlements through the 1930 Land Apportionment Act and later by the 1949 Forestry Act, 1951 Land Husbandry Act, and the 1975 Parks and Wildlife Management Act. The result was that people were physically and spiritually separated and settled in new areas with cultural heritage sites they were not directly associated with (Pwiti and Ndoro 1999; Ndoro 2001). The problem of isolating people from their cultural heritage appears to have been realized and addressed when the old plaques were replaced with appropriately rephrased ones, showing the new Act, CAP 313 (Fig. 3).

These brass plaques are still erected at many cultural heritage sites proclaimed as national monuments in Zimbabwe today. The problem of isolating the local communities from their cultural heritage appears to have been in principal addressed but in practice remained, even well after the independence of the country.

During its early formation, the Commission had felt that the enactment of the legislation was not adequate for the full protection of sites in the country. Physical intervention was therefore required in cases where sites would collapse or vandalized. An inspection program was established, and the work included carrying out regular inspection of all monuments, which included maintenance and repair (Fothergill 1953). Inspection reports, which outlined the conservation requirements of cultural heritage sites, were also introduced as part of the program. However, much of the early conservation work was technical and unsystematic and involved seasonal clearing of vegetation, restoration, and provision of access to the visiting public (Pwiti 1997; Ndoro 2001). At some sites such as Khami and Nalatale, concrete or cement mixed with earth (dhaka) was applied to stabilize the collapsing walls. This approach, however, focused more on the protection of physical aspects of cultural heritage sites, while the protection of intangible elements was not of major concern. Also, regular conservation work was biased towards bigger and popular sites such as Great Zimbabwe, Khami, Dhlodhlo, Nalatale, Tsindi, and Mtoko ruins. Smaller, less popular, and other type of cultural heritage sites were managed through a monuments inspection program. Some sites located in private farms such as Manyanga (Ntaba zi ka mambo) located in the former Meikles farm in the Bubi district were in part administered by the farmers themselves. Although there were attempts to manage some of the religious sites such as Njelele in the Matobo hills and Tere ruins in Mtoko, these sites remained under the custodianship of traditional authorities and community protection (Pwiti and Ndoro 1999; Ranger 1999; Makuvaza 2008).

Archaeological research at some of the sites led to the realization that they could be developed as major tourist attractions in the country. Consequently, site museums were developed during the colonial period and others after independence at or near sites such as Great Zimbabwe, Khami, Dhlodhlo, Nalatale, Mtoko, and Ziwa in Nyanga and in Matopos (Fig. 4). Exhibitions in these site

Zimbabwe: Cultural Heritage Management, Fig. 4 A museum at Khami developed as part of a visitor attraction at the site

museums, however, were largely targeted at foreign tourists and less at domestic visitors.

Many of these sites were, however, later abandoned at the height of the liberation struggle during the latter half of the 1970s for security reasons (Ndoro 2001). During this period, no conservation work was carried out, and vegetation, which had previously been regularly cleared, grew back threatening their structural stability.

Post-Independence Period

After independence, the approach to the management of cultural heritage in the country did not, however, differ much from that which was established during the colonial period. The legislation was amended in 1984, in 1990, and in 2001 during which year it was renamed CAP 25/11. Regardless of these amendments, the legislation remained to a very large extend identical to the predecessor Acts, especially in sections and parts that relate to the definition and the actual protection and management of cultural heritage in the country. After independence, the management of cultural heritage continued under the same conservative management structures, established during the colonial era.

Although there was not a marked difference between the management of cultural heritage during the colonial and independence periods, the new Zimbabwean government began to support its management throughout the country. More attention, however, was given to Great Zimbabwe which was viewed as a source of national pride and from which a new identity could be advanced (Pwiti 1997). Several international consultants were sent to Great Zimbabwe and other sites by UNESCO, UNDP, and by other European countries such as United Kingdom, Sweden, and Norway to provide advice on how they should be managed (cf. Ndoro 1997, 2001). This eventually resulted in the acknowledgement by UNESCO of the significances and values of Great Zimbabwe and Khami as universally outstanding, leading to their proclamation in 1986 as World Heritage sites. This was followed later by the proclamation of Matobo Hills in 2003, while Ziwa has been under consideration for World Heritage listing since 1997. Other monuments and sites continued to be managed through a revived monuments inspection program as was the case before independence.

In 1991, the NMMZ developed a Master Plan for Cultural Resource Conservation and Development, which was aimed at providing a national conservation strategy and development of some of the monuments as tourist attractions so as to generate revenue for the organization (Collett 1991). The master plan was also aimed at changing museum displays and at addressing local communities concerns. After independence, presentations of major monuments had remained targeted at foreign tourists, and the local communities had

also remained alienated from the management of these sites (Pwiti 1997). To address some of these concerns, a number of sites were selected for development, including Khami, Dhlodhlo, Domboshava – a rock art site situated 35 km north east of Harare and Old Bulawayo – a nineteenth-century Ndebele settlement located about 25 km south of Bulawayo.

While efforts were made to improve the management and development of important archaeological sites in the country, cultural heritage related to colonialism did not receive similar attention. Upon independence, the new government thought to be responsive to Black people's sensitivities could not allow cultural heritage related to colonialism to continue to survive (Turnbridge 1984). In Harare, this resulted in the removal of the statue of Cecil John Rhodes from Africa Unity Square and from the city center in Bulawayo (Fig. 5). The statue was viewed as symbolizing colonialism and oppression.

Keeping the statue in public places would have been interpreted as glorifying the colonial past and reminding Zimbabweans of the bitter colonial era under the British settler government rule. In Bulawayo, the statue was placed behind the premises of the Natural History Museum in the Centenary Park, away from public view. Plans are now at an advanced stage by the NMMZ to erect the statue of Joshua Nkomo at the position where Rhodes' statue once stood. Nkomo was one of the Zimbabwean nationalist who helped lead the war of independence against White minority rule in the country. About a decade ago, demands were also made by Sangano Munhumutapa, a pressure group, to exhume Cecil John Rhodes' grave in Matopos and repatriate the bones to Britain (cf. Muringaniza 2004). The NMMZ, however, intervened and saved the grave from this planned action, arguing that the monument is an integral part of the country's history.

On attainment of independence, many historical buildings have been threatened by modern development alleged to have been hindered by colonialism. Some of the buildings which had symbolized the settler government and oppression were owned by people of European origin, and Black Zimbabweans who could not own them did not have an interest in their protection. Instead, they were increasingly disturbed by the colonial repression the buildings symbolized and actively questioned the cultural heritage which was being protected in those structures (Turnbridge 1984). The interest in the protection of historical buildings appears to have been gradually lost due to the collapse of the Advisory Committees, as the few interested Whites left the country at the beginning of the land reform program in 2000. From 2000, the Zimbabwean government embarked on a compulsory "fast track" acquisition of White-owned farms and redistributed them to "landless" Black Zimbabweans. The legislation has also remained passive on the protection of historic buildings as a result of the increased demand for modernization of old buildings to accommodate present economic and public needs.

Zimbabwe: Cultural Heritage Management, Fig. 5 The statue of Cecil John Rhodes erected during the colonial period, between Main Street and 8th Avenue in Bulawayo

Few cultural heritage sites were proclaimed as national monuments in the country after independence. In the recent past, Mataga and Chabata (2008) examined the current NMMZ monument register, and they found out that the majority of sites were declared before independence and the rate at which these sites were listed dramatically declined after 1980. They noted that by 2006, of the 171 sites on the list, only seven were declared after independence, a surprising development given the change from the minority to the majority government. This is also notwithstanding the fact that a lot of sites have been found through archaeological research following the introduction of the archaeology program at the University of Zimbabwe early after independence.

The acquisition of White farms resulted in unemployment, reduced gross domestic product, deteriorating race relations, political and economic instability, and skills emigration. Subsequently, European states and the USA imposed "targeted" or "smart" sanctions on the country as a punitive measure of forcing the government to impede what they regarded as unwarranted land reform program and human rights abuse during elections. The worsening economic situation resulted in the departure of experienced archaeologists and cultural heritage managers to work in neighboring countries. The official household redistribution of land and the informal resettlements must have seriously impacted negatively on the protection of cultural heritage in the country. The hustle with which the land acquisition program was carried out meant that there was no time to protect cultural heritage during the land reform program.

The high unemployment rate resulted in the widespread of illegal mining named *Chikorokoza* of diamond known locally as *Ngoda* and gold in previously protected farms and along the country's Great Dyke. Cultural heritage sites could be destroyed through this illegal mining, probably taking advantage of the fact that mining legislation overrides the protection of cultural heritage in Zimbabwe. The Great Dyke is a linear intrusion of mafic and ultramafic rocks which cut across the Archaean granites and greenstones of the Zimbabwe craton in a SW-NNE direction. It is between 520 and 550 km in length and 4–11 km wide and is rich in ore deposits, including gold, silver, chromium, platinum, nickel, and asbestos (Wilson and Prendergast 2001). The impact that the land redistribution program and these mining activities had on cultural heritage is at present unknown as no impact studies have been carried out.

Strained international relations also led to either the withdrawal, cancellation, or drying up of donor funds for the management of cultural heritage in the country. Previously, cultural heritage management in Zimbabwe depended much on donor funding. The major problem of the withdrawal or cancellation of donor funding is that it placed the entire cultural heritage management into an uncertain future (Murimbika and Moyo 2008). The prevailing harsh economic environment also resulted in continued business depression leading to the withdrawal of local aid support for cultural heritage management. Consequently, cultural heritage management has been greatly underfunded in the country.

Future Directions

Way Forward and Conclusion

There have been expectations that cultural heritage management in Zimbabwe should be improved. These hopes have been based on the knowledge that cultural heritage has not been efficiently managed during both the colonial and postcolonial periods. The expectations have also been that the improvement should be in line with the shifting meaning of cultural heritage and the best international management practices. The failure to improve the management of cultural heritage in Zimbabwe has been regarded by Pwiti and Ndoro (1999) as the perpetuation of the colonial legacy.

To improve the management of cultural heritage, it has thus been argued that the legislation governing cultural heritage management should be revised. This would address the problem, according to Chipunza (2005) of its entrenchment in colonial principle, which considers that cultural heritage sites should be protected rather than used.

This would also address the problem of the isolation of the local communities from managing their cultural heritage and the protection of its intangible aspects. The overlap of duties that were created between the NMMZ and the Park authorities since from the 1950s would as well be addressed through the revision of the legislation. The rampant destruction of cultural heritage through mining ventures could be avoided if reference is made to its protection under the mining legislation. Contracts for the NMMZ administrators require to be shortened to avoid the pursuance of self-interests and style of management, which can negatively affect the proper management of cultural heritage. This would end the current conservative approach to the management of cultural heritage in Zimbabwe.

Introduction

Zimbabwe has five World Heritage sites, which are Great Zimbabwe, Khami, Matobo Hills, Victoria Falls, and Mana Pools. The Nyanga Terraces are on the Tentative List (Fig. 1). Great Zimbabwe, Khami, and the Nyanga Terraces are managed by the National Museums and Monuments of Zimbabwe (NMMZ), while the Victoria Falls and Mana Pools are run by the Zimbabwe Parks and Wildlife Management Authority (ZPWMA). The Matobo Hills are managed by both the NMMZ and the ZPWMA. These sites have a long history of research, conservation, and development well before they were accorded World Heritage status.

Key Issues/Current Debates/Future Directions/Examples

Great Zimbabwe

Declared the second national monument in 1937 after Victoria Falls, Great Zimbabwe (CE 1290–1450) is located near the city of Masvingo in south central Zimbabwe. It is one of the best-known archaeological sites in sub-Saharan Africa (Fig. 2). The site was established following the demise of Mapungubwe (CE 1220–1290), a precolonial site, situated at the confluence of Shashe and Limpopo rivers in the south. It consists of dry-stone walls and several Dhaka (earthen) structures of different sizes. Great Zimbabwe is divided into three main areas: the Hill Complex, the Valley Ruins, and the Great Enclosure. Two perimeter walls separate the inside and external confines of the settlement (Ndoro 2001).

At its peak, between the fourth and fifteenth centuries, its population probably numbered 18,000 people, settled over an area of more than 720 ha (Huffman and Vogel 1991). The site was perhaps the largest settlement in sub-Saharan Africa before European colonization of the region (Ndoro 2001).

The decline of Great Zimbabwe as a center of a powerful prehistoric state between CE 1450 and 1550 remains an unresolved archaeological problem. According to Pikirayi (2001), this is largely due to unsystematic investigations of the late nineteenth century European antiquarians and prospectors, who destroyed its stratigraphy and looted the site in search of Near Eastern artifacts and gold. The site was abandoned by the middle of the fifteenth century. Causes for the abandonment have been suggested to be the decline of trade, which had shifted to the north of the country, political instability, famine, and water shortages caused by climatic change (Garlake 1982). However, the demise of Great Zimbabwe led to the rise of two major polities; the Mutapa state in the north and the Torwa state in the west.

During the late nineteenth and early twentieth centuries, Europeans who encountered Great Zimbabwe caused great controversy among the archaeological world. They contended that the site was not built by the indigenous people because of its advanced architecture. They thus attributed its construction to the Phoenicians, Arabians, or Egyptians (Mahachi and Ndoro 1997).

According to Huffman and Vogel (1991), this hypothesis was based on superficial similarity

Zimbabwe's World Heritage Sites, Fig. 1 Map showing the location of world heritage sites in Zimbabwe

Zimbabwe's World Heritage Sites, Fig. 2 Conical Tower in the Great Enclosure

between the site and the ruins in southern Arabia and false resemblance in names such as Ophir and Fura (also called Mount Darwin). The Rhodesian government also mounted political pressure on archaeologists to deny the authorship of the site by the indigenous people to justify its colonization of the country (cf. Mahachi and Ndoro 1997). This view, however, changed with the arrival of the first systematic archaeologists from the 1920s onwards. Evidence which demonstrated that the site was constructed by the indigenous people was largely based on the stratigraphical evidence at the site and comparative research carried out at Khami and Dhlodhlo (Danan'ombe) (cf. Caton-Thompson 1931; Robinson 1959). From this archaeological research, it was ultimately concluded that the indigenous people of Zimbabwe were responsible for the construction of the settlement.

Since from the late nineteenth century, archaeological research was carried out alongside conservation of the site, which began as far back as 1914 (Ndoro 1994). Much of it was, however, technical and unsystematic (Pwiti 1997; Ndoro 2001). Major restorations of collapsed stone walls were carried out on different parts of the site and approached from misinformed interpretation of the site. This is because the site was viewed as a product of exotic populations rather than of the indigenous people (Pwiti 1997). At independence from the British settler government in 1980, the country was named Zimbabwe after this archaeological site. Once the authorship of the site was resolved, not much archaeological research has been carried out at the site, and the focus shifted to its conservation and management. Accordingly, the government began to support the management of the site as it was viewed as a source of national pride and from which a new identity could be forged (Pwiti 1997). Several international consultants were sent to Great Zimbabwe by UNESCO and UNDP and by many European countries to provide advice on how it should be managed (cf. Ndoro 2001). This eventually resulted in the acknowledgement by UNESCO of its significance and values as universally outstanding leading to its proclamation in 1986 as a UNESCO cultural World Heritage site.

Khami

This archaeological site is a complex of dry-stone walls that cover approximately 35 ha of land and is located 22.5 km west of Bulawayo. Khami was established as a Torwa state in around 1640 after the collapse of Great Zimbabwe. The distinct development of Khami state was a modified style of dry-stone wall architecture, which was inherited from the Great Zimbabwe architecture. Its structures are terrace or retaining walls that are constructed around and over granite hill tops. The top surfaces of the hill tops were leveled to create platforms at which residential houses were built (Robinson 1959). The platforms are also decorated with check and cords patterns, and the general layout of Khami is a clear testimony of the continuity from the preceding site of Great Zimbabwe (Fig. 3). The site has seven built-up areas believed to have been occupied by the royal family, with open areas in the valley occupied by the commoners.

The wealth of the Torwa state in cattle and involvement in long distance trade was envied by other ethnic groups. This eventually led to the invasion of the site in around 1683 by a powerful Rozvi people. This led to the burning and abandonment of the Torwa capital and the shift of the state to Dhlodhlo (Danan'ombe), located approximately 100 km in the east.

The archaeological footprint, which was protected as it was the royal reserve for Lobengula, the Ndebele King, was not badly disturbed by rampant prospecting by treasure hunters of the Rhodesia Ancient Ruins Company Limited. The site was examined by Randall-MacIver (1906), by Gertrude Caton-Thompson (1931), and by Robinson (1959), with the major aim of resolving the authorship of Great Zimbabwe. However, this work also provided comprehensive knowledge about the site's history. Since then, like at Great Zimbabwe, not much archaeological research has been carried out at the site as attention shifted to its conservation and protection. In 1937, Khami was proclaimed as a national monument in recognition of its importance in the prehistory of the country. Its significance was, however, eventually acknowledged as universally outstanding leading to its proclamation as

Zimbabwe's World Heritage Sites, Fig. 3 The restored Hill Complex at Khami

Zimbabwe's World Heritage Sites, Fig. 4 The Matobo Hills cultural world heritage landscape

a UNESCO cultural World Heritage site in 1986, the same year Great Zimbabwe was also accorded with the same status. Even though there are efforts which are being made to protect the property, the site is threatened by the constant flow of sewage into Khami River and dam due to the expansion of the Bulawayo high density suburbs towards this World Heritage site.

Matobo Hills

The Matobo Hills are located in Matabeleland South Province, about 35 km south of Bulawayo. They measure about 3,100 sq. km, extending from almost to the Botswana border in the west, while to the east they merge with the Mbalambala granite pluton (Fig. 4). The local people also refer to this cultural landscape as Matonjeni.

The natural landscape comprises of scenic geological formations, which provides a wide range of niches that support a variety of flora and fauna. The geomorphology of the hills gives rise to microclimates and soil conditions which change markedly over short distances. The resultant landscape comprises of extensive open grasslands with groups of kopjes (rock outcrops) which are interspersed with wetlands (marshes and streams). The combination and diversity of flora and fauna and its long history of interaction with humankind has made this cultural landscape worthy of attention and preservation (Walker 1996).

Archaeological evidence has shown that the hills have been inhabited from the Stone Age period right up to the present times (Walker 1996). The hills have probably the highest concentration of rock art in southern Africa. This testimony, which when combined, contributes to the understanding of the precolonial history of the region. Matobo is the abode of the oracular cult of the High God (Mwari/Mwali) whose voice is believed to have been heard from the rocks (Ranger 1999). This oracle links the local communities with the hills. The hills also contain important historical sites from the colonial and postcolonial periods. Archaeological research in the Matobo has been more focused on the Stone Age period and the historical period as well as its biodiversity (see Grobler 1974; Walker 1996). However, not much research has been carried out on the Iron Age period of the hills. Although this is the case, the hills were accorded World Heritage status in 2003, making the area the first cultural landscape to be honored with this importance in the country.

The management of the hills has a long history, dating back to a period before the arrival of Europeans in the area in the late nineteenth century. Before this period, the hills have been managed by traditional methods and laws (cf. Ranger 1999). With the coming of Europeans, new laws based on European notions of management were introduced. Today, the management of this cultural landscape is based on the combination of traditional practices and modern legislations.

Victoria Falls

The Victoria Falls were inscribed on the World Heritage list in 1989 as a transboundary property shared between Zambia and Zimbabwe. This site is located in southwestern Zambia and northwestern Zimbabwe.

At Victoria Falls, the Zambezi River course is interrupted by the falls at approximately 1,300 km from the river's source in the northwest province of Zambia (Fig. 5). Below, the river traverses for another 1,500 km to its delta on the Indian Ocean

Zimbabwe's World Heritage Sites, Fig. 5 The Victoria Falls world heritage site main falls

in Mozambique. In 1855, the Victoria Falls was named by a Scottish missionary-explorer, David Livingstone, in honor of the British Queen Victoria. The falls are also known by their local Kololo name, Mosi-oa-Tunya, meaning the "smoke that thunders" because of the water's roar and clouds of rising mist.

The management and development of Victoria Falls as a tourist resort began from 1900 soon after the eviction of the local communities from the area (see McGregor 2003). On the Zambian side, the management of the Victoria Falls began in 1934 when an Executive Committee was set up under the Victoria Falls Reserve Preservation Ordinance. Its objectives were to promote tourism by managing visitor rondavels previously located at the now defunct Rainbow Lodge as well as managing the Zambia hydropower station and the customs post. Subsequently in 1948, the Preservation of Natural and Historical Monuments and Relics, which is now the National Heritage Conservation Commission, set up a Conservancy Committee. In the following year, the committee enacted bylaws and extended the protected area to the Songwe Gorge, which is just below the falls. On the Zimbabwean side, the Victoria Falls Reserve Preservation Act was enacted in 1928, specifically to protect the Victoria Falls Reserve, known as the Special Area (Fig. 6). A new legislation called the Monuments and Relics Act was enacted in 1936. This followed the establishment of the Commission for the Preservation of Natural and Historical Monuments and Relics, popularly known as the Commission, which is now the NMMZ. A year after, in 1937, the Victoria Falls Reserve was proclaimed the country's first national monument. In the same

Zimbabwe's World Heritage Sites, Fig. 6 The Victoria Falls special area proclaimed as Zimbabwe's first national monument in 1937

year, bylaws were put in place to protect the area (Joint Technical Committee 2007). At present, there are numerous related legislations being implemented at the site.

With the growth of heritage tourism, which is a special interest travel, which ranges from the examination of physical remains of the past and natural landscapes to the experiencing of local cultural traditions, the Victoria Falls have become a popular tourism area. Visitors to the site are motivated by unique experience, exclusivity, differentiation, personal experiences, and nostalgia for the past and the desire to experience diverse landscapes and forms. Until a few decades ago, the only important tourism activities at the site were to walk and view the falls and gorges from a few selected points. In recent years, however, a broad range of activities have been offered within the World Heritage area to cater for the different needs of visitors. In view of that, the site is currently being threatened by the expansion of tourism facilities (Joint Technical Committee 2007).

Also in recent years, the NMMZ and the ZPWMA have been involved in an ownership dispute of the Special Area. The NMMZ argues that the Special Area is the country's first national monument under the then Commission and should be returned, while the ZPWMA counter argues that the area is now part of the Victoria Falls National Park, which was established in 1952 and it now falls under its administration. Although this conflict is yet to be resolved, it has caused considerable management problems of this celebrated World Heritage site (cf. Makuvaza 2010).

Mana Pools

The Mana Pools were the first to be proclaimed in 1984 as a UNESCO natural World Heritage site in Zimbabwe. The site is located in the Hurungwe district in Mashonaland Province. It is composed of three adjoining protected areas, namely, the Mana Pools National Park, Sapi, and Chewore Safari Areas.

This World Heritage site is part of the Miombo woodland/savannah biogeographic territory. The area includes large areas of the rugged Zambezi escarpment and also contains the last remaining natural stretch of the middle Zambezi River. Well-grassed Brachystegia communities dominate the mountainous escarpment and higher Chewore areas with small but significant riparian communities along the numerous streams. The valley is dominated by the mopane (*Colophospermum* spp.) woodlands. There is also a wide range of large mammals, over 350 bird species and aquatic wildlife in this World Heritage site.

The property has a well-defined and buffered boundary. Each of the three areas has functional park management plans. However, the site does not have an integrated site management plan to ensure the effective management of the property.

Conservation problems affecting this World Heritage site, which are pollution and uncontrolled exploitation of its resources, have not been fully addressed since from early 1990s when an environmental impact study for the proposed Mupata hydroelectric power generation was carried out (see du Toit 1982). For engineering reasons, the Mupata project was shelved and a new feasibility study was carried out at Batoka Gorge. However, both projects appear to have been shelved as well given the economic and political problems experienced in the country in recent years. The site has also continued to be threatened by poaching, sport hunting, boating, and fishing. It is also regularly threatened by the regulating effect of the Kariba Dam and continued development of tourism facilities.

Nyanga Terraces

This cultural landscape, which is located in the Nyanga area in northeastern Zimbabwe, has been on the UNESCO World Heritage Tentative List since 1997. The cultural landscape has stone-faced terraces, which cover every hill and valley sides, while hundreds of hectares of soils have been worked into wide cultivation ridges. Associated with these are stone-built homesteads of the builders. Old water furrows reveal the exploitation of available water resources, and traces of iron-working show testimony of manufacturing activities. The cultural landscape covers a total of approximately 5,000 sq. km. The whole complex represents an agricultural society of industrious farmers and livestock herders whose culture developed from about CE 1300 to sometime in the

nineteenth century (Soper 2006). The terraces have evidence of human occupation for all the major archaeological periods identified in the country's archaeological sequence, beginning from the Stone Age to the historical period.

Since the placement of the terraces on the Tentative List, no effort has been made to ultimately inscribe them on the World Heritage List. Recently, however, the potential World Heritage status of the site has been noted (Willems and Comer 2011). If properly nominated, there is no doubt that the terraces can be Zimbabwe's next cultural World Heritage landscape.

Discussion and the Future

Although there is sufficient knowledge about sites such as Great Zimbabwe, Khami, and the Matobo Hills, a knowledge gap on how people moved from their old settlement to new established ones still exists. For instance, it is not clear if the movement of populations from Mapungubwe to Great Zimbabwe and from Great Zimbabwe to Mutapa in the north and to Khami in the west was rapid or gradual. If the movement was steady, settlements which are associated with this gradual process of movement require searching and further investigation. In Matobo, the transformation from the hunter-gatherer to the Iron Age period also requires further archaeological enquiry. Although a lot of archaeological research has been carried out on the Nyanga Terraces, there still exist areas that are not very apparent. The purpose for which the terraces have been constructed, and the recent discovery of gold mining by Kritzinger (2008) are still very highly controversial issues. At Victoria Falls, archaeological research was only active during the 1970s (see Phillipson 1975), while there is virtually no archaeological research carried out in the Mana Pools World Heritage area. As a result, not much is known about the prehistoric people who once settled in these natural World Heritage sites.

However, while this is the case, on the administrative side, there is also little or no effort made to fully involve the local communities in the management of these World Heritage sites. This explains why the integrity of some of them is constantly threatened. The friction between the NMMZ and the ZPWMA over the ownership of the Special Area needs to be resolved, while coordination with the Zambian authorities is vital to curb further development of tourist facilities in this World Heritage area. Lastly, efforts have to be made to nominate the Nyanga Terraces so that it can be added to Zimbabwe's rich and diverse natural and cultural World Heritage properties.

Zimmerman, Larry J.

Dorothy T. Lippert
Repatriation Program, National Museum of Natural History, Smithsonian Institution, Washington, DC, USA

Basic Biographical Information

Larry J. Zimmerman is a North American archaeologist who is known for his work in social justice as it relates to the practice of archaeology. Zimmerman received a Ph.D. from the University of Kansas in 1976 and taught at the University of South Dakota from 1974 to 1996, where he was Distinguished Regents Professor. He was Chair of the American Indian and Native Studies at the University of Iowa from 1998 to 2001 and was Head of the Archaeology Department at the Minnesota Historical Society from 2002 to 2004. Since 2004, he has served as Professor of Anthropology and Museum Studies and Public Scholar of Native American Representation at Indiana University-Purdue University, Indianapolis, and the Eiteljorg Museum of American Indians and Western Art in Indianapolis, Indiana.

Major Accomplishments

Zimmerman is highly regarded for his commitment to Native American and Indigenous issues as they relate to archaeology. In 1978, Zimmerman excavated the Crow Creek Massacre site in central South Dakota. His ability and willingness to listen to Lakota and Arikara Indian nations about their concerns over the project led him to insist on reburying the human remains that had been uncovered at the site. Three years of negotiations took place between the tribes, the Bureau of Indian Affairs, and the US Army Corps of Engineers before the remains were finally reburied. This project led to Zimmerman being trusted by many Native American activists but also put him in the middle of the controversy over whether repatriation and reburial could be a legitimate activity for a US archaeologist. Zimmerman's decision to speak with the descendants of the individuals buried at this archaeological site and ultimately to accede to their wishes with regard to treatment of the human remains resulted in hardships for him within the profession. Rather than hiding these challenges, he chose to publish accounts of them, such as the 1989 essay, "Made Radical by My Own," which were received as beacons by young Native scholars.

Zimmerman's publications revealed deficiencies in what was then standard American archaeology. The theoretical voids in American

archaeology that Zimmerman highlighted are what many archaeologists now stand proudly behind: the need for archaeology to be socially relevant and respectful. By assigning his support to the "radical" side, Zimmerman exposed himself to the potential of ridicule and derision by his peers. Zimmerman (1989b: 66) stated that, "I think being yelled at by colleagues and Indians is good for the soul," standing bravely behind his belief that being yelled at is a small price to pay for doing the right thing.

In 1988, Zimmerman served as Organizing Secretary of the World Archaeological Congress' First Inter-Congress in Vermillion, South Dakota. This meeting is important in that it resulted in one of the first archaeological codes of ethics to note the importance of treating human remains as inextricable from their cultural contexts, the Vermillion Accords. These set forth provisions for the ethical treatment of the dead by archaeologists and rest on the principle that human skeletons mean much more than archaeological objects. This was a watershed moment, representing the first time an international community of archaeologists listened to and reflected on the concerns of Indigenous peoples in an archaeological code of ethics. The fact that professional archaeologists from all over the world chose to travel to a remote area of South Dakota reflects the importance of the meeting. The Vermillion Accords have influenced generations of archaeologists and have meant that Native Americans have been able to see that a segment of the archaeological population really does understand deeply held tribal concerns about human remains and burial sites.

More recently, Zimmerman has been involved in a project of archaeology of the homeless, conducting research in downtown Indianapolis, Indiana, USA. The homeless archaeology project provides useful information for city governments and social workers who may have lacked an understanding of what life is really like for the homeless. Similar to Zimmerman's work with Native American communities, this research takes place alongside members of homeless communities. It is a collaborative research and also a form of social justice. These themes pervade most of Zimmerman's work.

Zimmerman's professional service includes work for the Society for American Archaeology, for which he served as a member of the Nominating Committee (1994) and as the chair of the Native American Scholarships Committee (1995–1997). He has also served the American Anthropological Association as elected Chair of the Committee on Ethics (2002–2005). Much of Zimmerman's professional service has been for the World Archaeological Congress, for which he has served as Executive Secretary from 1990 to 1994 and as Vice President from 2005 to 2008.

In addition to the Vermillion Inter-Congress held in 1988, Zimmerman organized the World Archaeological Congress' 2009 Inter-Congress on Indigenous Peoples and Museums, held in Indianapolis, Indiana, USA. This conference provided space for ongoing dialogue about topics such as repatriation, the differing national ethics of museum exhibits, and ways that Indigenous knowledge can enhance archaeological research. It is certain that Zimmerman's reputation was one of the big draws for the meeting. In the 23 years since the Vermillion Inter-Congress, American archaeology has undergone a shift. Today, there are more than 17 Native Americans who hold doctorates in archaeology and many more with Master's degrees. In addition, the attitude and spirit of the Vermillion Inter-Congress is expressed in mainstream archaeology through the practice of what is called "Indigenous archaeology." If Zimmerman had not set the groundwork back in 1989, there certainly would never have been a 2009 conference of this nature. And, many of the subjects that were discussed might never have been raised.

Zimmerman has been honored by many organizations, including the Indiana University-Purdue University, Indianapolis, where he was named Outstanding Distinguished Resident Faculty, School of Liberal Arts in 2009. He was awarded the Mariko Mizuhara Award for Cross-Cultural Understanding in 2000 from the University of Iowa. Notably, in 2008, he received the inaugural Peter J. Ucko Memorial Award for Contributions to World Archaeology from the World Archaeological Congress at the sixth Congress in Dublin, Ireland. In a reflection of how his work

has affected North American archaeology, Zimmerman was nominated for this award by four Native American archaeologists who hold doctorates. Each nominator was able to reflect on how Zimmerman's work had allowed them to progress within the discipline of archaeology.

Larry Zimmerman's commitment is not to archaeology of the dead, but to archaeology for the living. In his work with Native Americans, he sees us as inextricably linked to our ancestors and does not conduct work without acknowledging this bond. In his work with the homeless, he sees the path between the data he accumulates and the process of changing the lives of the people who live on the street. His archaeology is not conducted in an academic vacuum. He realizes that archaeology is a science that can be a powerful force for good.

Zoning: Boundary Areas and Buffer Zones

Douglas C. Comer
ICOMOS International Scientific Committee on Archaeological Heritage Management (ICAHM), Cultural Site Research and Management, Inc. (CSRM), Baltimore, MD, USA

Introduction

In the sense that time, as a quote widely attributed to Woody Allen would have it, is nature's way of keeping everything from happening at once, so

zoning is a scheme devised by humans to prevent everything from happening at the same place. On any landscape, some areas are more amenable to particular uses than are others, and uses in some areas can be complementary or incompatible. When the landscape contains archaeological sites and materials that can be damaged by certain forms of human activities, preservation of them depends upon allocating, or zoning, uses appropriately. Effective conservation and preservation at archaeological sites must draw upon the knowledge of where vulnerable archaeological resources are located. Zones can then be delineated in ways that can be easily used by site managers.

Definition

Zoning is a basic land management tool, one commonly employed by local and regional governments in developed countries around the world. Zoning as practiced in settings from urban to rural addresses a variety of issues associated with use: activities (residential, commercial, industrial, agricultural), density of use or development, height of buildings, limitations on built space per unit of landscape, limitations on area of impervious surface, construction of roads and parking lots, preservation of green space, and rules governing both architectural and landscape design.

Key Issues/Current Debates/Future Directions/Examples

Many organizations that play a role in the conservation and preservation of archaeological sites have been slow to apply the concept and protocols of zoning. The idea of a buffer zone around World Heritage Sites was not introduced into the *Operational Guidelines for the Implementation of the World Heritage Convention* until 1977. In the 2005 version of these guidelines, a buffer zone was strongly recommended, but not mandatory. In 2008, an International Expert Meeting on World Heritage and Buffer Zones was held in Davos, Switzerland, which introduced less equivocal language into the Operational Guidelines (UNESCO 2012: Paragraphs 103–107). It defined a buffer zone as an area surrounding a property necessary to the proper conservation (used in this sense to include preservation) that has been established by means of legal or customary restrictions. It should constitute an added layer of protection around the property. The buffer zone is described as (including), "the immediate setting of the nominated property, important views and other areas or attributes that are functionally important as a support to the property and its protection" (UNESCO 2012: Paragraph 104). Sites nominated to the World Heritage List, according to this version of the guidelines, must include a map of the buffer zone and a clear description of the size, characteristics, and uses authorized in the buffer zone. The guidelines also state that the buffer zone be determined through "appropriate mechanisms" and that the purposes served by the buffer zone be described.

In the publication resulting from the experts meeting (UNESCO 2009), it is emphasized that a buffer zone be defined in legal terms, "not just in the World Heritage nomination dossier" (UNESCO 2009: 29), thus emphasizing that such a zone should exist as more than a name alone. The document also suggests that the zone be devised in mind of all forms of intrusion to the site, including acoustic and visual, as well as those which arise from construction, roads, vibration, and natural disasters. It also notes that the buffer zone should be part of the management plan or system for the protected area, that is, the buffer zone itself must be managed and management should be integrated with that of the site itself.

The Xi'an Declaration (UNESCO 2005) also addresses the subject of buffer zones, here in the context of the preservation of setting. The need for monitoring change is expressly presented: "Monitoring should define approaches and actions to appreciate and measure as well as prevent or remedy decay, loss of significance or trivialization and propose improvement in conservation, management and interpretation Practices" (UNESCO 2005: 3). It sets out the need for the development

of qualitative and quantitative indicators for this purpose. This is consistent with protocols for monitoring as they are used in many other fields, including ecology and medicine, which stipulate that instruments, indicators, and standards be identified in a monitoring plan (Comer 2006). Instruments are the means by which change is measured (e.g., a series of photographs or samples taken over time, periodic surveys of visitors to the site and residents of local communities). Indicators are things to be measured, which should be selected because they are most relevant to the condition of the system of which they are a part (e.g., indicator species in ecology, cholesterol or blood pressure in medicine). Finally, standards are thresholds that when crossed produce damage to the system in question.

Clearly, a buffer zone can be considered just the first step in establishing zoning adequate for effective management of an archaeological site or, indeed, any protected area. Other organizations with stewardship responsibilities for areas containing vulnerable natural and cultural resources have extended zoning in ways similar to those used by local governments in developed countries. For example, the Visitor Experience and Resource Protection Framework that has been used by the United States National Park Service since 1997 relies heavily on the concept of zoning (United States National Park Service 1997). Zones are determined by an analysis of the distribution of cultural and natural resources, the environmental context in which they are found, the degree to which they are sensitive to damage or destruction by human use, and existing infrastructure. This analysis is conducted after extensive research, which includes review of scientific literature and interviews with subject matter experts and all parties with a legitimate interest in the protected area. Of particular importance to achieving the goals of the framework is consultation with local communities and any indigenous peoples associated with the area in question. For each zone, the desired use and the desired condition are established. These can vary widely. Areas that provide essential visitor amenities, for example, should not be located in zones that contain sensitive resources. Some sections of archaeological sites can best be appreciated and understood in relative solitude; others, for example, the bustling city centers of the ancient world, can be experienced best in the presence of others. The VERP approach also emphasizes the need to monitor both resource conditions and the satisfaction of visitors and residents alike.

The effective management of an archaeological site benefits greatly from zoning, and at large archaeological sites, it is likely that this cannot be achieved without zoning. As time goes one, zoning similar to that done by developed countries in urban and suburban environments should become standard practice.

Zooarchaeology

László Bartosiewicz
Osteoarchaeological Research Laboratory, Stockholm University, Stockholm, Sweden

Introduction

Animals have played key roles in society, evolving alongside people from the Paleolithic right up until today. First they served as a source of food: animals were killed or scavenged for their meat, fat, and marrow as well as their skins and bones for manufacturing. Since domestication, renewable secondary products such as milk, wool, or labor have also been provided by animals. Alongside practical innovation, perceptions of animals also evolved into a range of often subtle varieties. Human-animal interactions are therefore of utmost interest in reconstructing ancient cultures. Moreover, animals are often used as media conveying messages that reflect relationships between people: they have formed an integral part of our mentality. Animal remains are usually brought to light in substantial quantities during archaeological excavations. As such, they potentially offer statistically reliable information on how humans interacted with their environments and with one another.

Definition

Zooarchaeology, originally called archaeozoology in the Old World, considers relationships between humans and animals using animal remains from archaeological sites. Although rooted in paleontology, the study of fossils from extinct natural fauna, zooarchaeological research deals exclusively with evidence from archaeological contexts. It is a multidisciplinary subject: it may involve the analysis of related objects (e.g., hunting gear or harnessing) and integrate the evaluation of excavated materials with pictorial and written records. Zooarchaeology thus addresses diverse problems, from the biological and environmental aspects of past cultures to the social and cognitive side of human-animal relationships.

Historical Background

In his review of zooarchaeology in eastern North America, Neil D. Robison (1987) outlined three periods also applicable to Europe. Developments after the 1980s form the fourth, most recent phase.

The Formative Period (1850s–1951)

Archaeozoology emerged in mid-nineteenth-century Europe. It first developed in areas where spectacular architecture, hoards, and written sources did not distract attention from gathering complementary information in the form of biological remains. In 1851, Japetus Steenstrup began studying massive "shell banks" in coastal Denmark. Recovering archaeological artifacts and animal bones, he realized that these masses of shell were food refuse and coined the term "kitchen midden" (*køkkenmødding;* Forchammer et al. 1851–1856). Soon similar formations were studied along the Atlantic coasts of Europe and North America (Wyman 1868).

Archaeology in the nineteenth century was also inspired by romantic nationalism. Communal identities were asserted by claiming ancestral lineages. Celts, Etruscans, and other putative ancestors were studied across Europe. Help by Ludwig Rütimeyer was enlisted in a quest for Celtic Helvetii at Swiss lakeshore settlements. Although many of the pile dwellings turned out to have been much earlier (Neolithic and Early Bronze Age), Rütimeyer (1861) came up with a scholarly analysis of animal remains which, according to Darwin, represented "the most important contribution on domestic races ever published."

In 1865, Rudolf Carl Virchow – pathologist, politician, and polymath – had high hopes of having discovered yet another prehistoric pile dwelling in central Berlin which turned out to be an early eighteenth-century urban deposit. Among others, he identified evidence for seafood consumption which predated the first eighteenth-

Zooarchaeology, Fig. 1 The distribution of first–third century Roman provincial dogs by estimated withers height and forearm shape (relative breadth of radius) from Pannonia and Germania in comparison with modern breeds. Propagating an inherited, nonpathological deformation through breeding created a range of short-legged forms toward the upper left corner of the graph (after Bökönyi 1984; Peters 1997)

century Hamburg postal regulation concerning oyster barrels shipped to Berlin (Virchow 1872: 124). In this earliest example of postmedieval archaeozoology, Virchow struck the delicate balance between naturalists and culture historians, identifying lowly kitchen garbage of no interest to historians as "luxury artifacts" carrying historical meaning. In 1874 Virchow began working with Heinrich Schliemann at Troy.

Darwin's 1868 book on the variability of domesticates directed attention to an important point central to zooarchaeology: domestic animals are material culture since they are shaped by human needs, beliefs, and aspirations. Human influence on their genetic makeup was not always conscious but is characteristic of the social niche the animals occupy – driven by cultural forces that can be detected in the shape and size of bones (Fig. 1). Ulrich Duerst (1926) adopted Rudolf Martin's standardized human bone measurement system for a wide range of mammals.

Systematization Period (1951–1969)

Following World War II, the first generation of full-time zooarchaeologists emerged, including Jesús Altuna, Joachim Boessneck, Sándor Bökönyi, Vera Issacovna Gromova, John E. Guilday, Johannes Lepiksaar, Stanley J. Olsen, Elisabeth Schmid, Rudolf Stampfli, to name just a few.

By this time, domestication was recognized by archaeologists as a benchmark in the development of civilization. The origins of most Old World domesticates have been traced back to the Neolithic of the "Fertile Crescent" (including the Levant as well as the Taurus and Zagros mountains ranging between Anatolia and Iran). The formation and distribution of domestic animals across Europe dominated the agenda, reinforcing the misconception that zooarchaeology was a "prehistoric" discipline. Under the influence of ethnographic research, the need to quantify animal remains arose. Theodore E. White (1953) came up with the concept of Minimum Number of Individuals (MNI). Much of the work at the time was aimed at reconstructing animal keeping rather than consumption. The mentality that focused on individuals and resulting herds populating catchment areas of sites leads to the development of a "herd management" jargon including harvest profiles and herding strategies. This language, however, although pervasive, remained

largely allegoric in the face of typically sporadic archaeological evidence. Little critical attention was paid to the impact of site formation processes on the reliability of data.

Integration Period (1969–1980s)

The invention of MNI already indicated the intellectual need to understand zooarchaeological data in more exact, economic terms, pushing interpretation beyond the physical descriptions of ancient animals. The archeological aspects of animals began to be treated at a new scientific level (Brothwell & Higgs 1969).

Radiocarbon dating at stratified settlements helped to clarify the pace of domestication in the Near East (Braidwood 1963). Scientific expectations culminated in "New Archaeology" aimed at treating archaeology as a natural science. With their positivist agenda, archaeologists discovered the wealth of information represented by animal bones, treating them from a primarily archaeological point of view. Previously archaeozoology was largely practiced by natural scientists; zooarchaeology represents the same discipline, but the emphasis is on archaeology.

Environmental thought on the rise during the 1960s soon inspired archaeological interpretation. Animal remains were tentatively included among ecofacts as materials not directly altered or modified by humans but associated with human exploitation (Schiffer 1987: 290–291). However, zooarchaeological finds by definition (i.e., in their connection to human cultural contexts) incorporate an artifactual dimension just like properly manufactured, even artistic bone objects or the genetic makeup of domesticates. Anthropogenic influences can create considerable bias in the environmental interpretation of animal remains from archaeological deposits.

New Archaeology (subsequently morphing into processual archaeology) set very high standards to present archaeology as a natural science. The processual paradigm includes the use of quantitative data in deductive models, the scientific method of observation, and hypothesis testing. Zooarchaeology has greatly benefited from this ambition: quantitative methods had long been around, but the novelty was that in addition to taxonomic composition or reconstruction of animal size, the degrees of fragmentation and dispersal were recognized as characteristic of ancient cultural behavior. Proponents of New Archaeology applied concepts from a variety of fields such as middle-range theory, adopted from sociology by Lewis Roberts Binford. Middle-range theory proceeds from an empirical phenomenon toward general statements to be tested using data. Binford carried out ethnoarchaeological fieldwork among the Nunamiut and Navajo in North America, as well as in Australia, applying archaeological ideas and methodology to the analysis of contemporary animal bone refuse. By describing how modern people handle similar objects, he linked their use to archaeological interpretation (Binford 1981). In the case of direct ethnographic analogy, continuity in ancient practices can be documented. In the absence of cultural continuity, analogies remain indirect: in addition to morphological similarity between the archaeological and modern artifact, a reconstruction of technological/cultural contexts is necessary (Fig. 2).

Worked bones, traditionally treated as "real" artifacts, were studied by archaeologists from a purely stylistic point of view, rarely falling into the purview of zooarchaeologists. The 1957 book *Prehistoric Technology* by Sergei Aristarkhovich Semenov (1964) was translated into English and became very influential during this period. Zooarchaeologists became more directly involved with analyzing worked osseous materials in the late 1970s thanks to the application of new models, integrating archaeological, zoological, and technical information.

Opponents to the processual approach have emphasized that archaeological data are not reproducible and usually of too poor quality to meet the criteria set by the logical positivism of "hard" science. By the late 1980s, postprocessual archaeology, a variegated rebound effect to failed scientific methodology was largely united only in its rejection of such methods. This trend took a toll on the demand for zooarchaeology that had been so appreciated by the processualist school. Animal bone reports became mere appendices to archaeological analyses (with little effort to integrate their conclusions), or published as case

Zooarchaeology, Fig. 2 Late fifteenth-century Inka Period llama metapodium bone point from Paria, Oruro Province, Bolivia (left), and its modern counterpart (right) being used by a local villager. In the absence of direct cultural continuity, aside from morphological similarities, the raw material, use wear, and functional context need to be carefully considered

studies in specialist journals, separated from mainstream archaeological discourse. Rarely, zooarchaeological monographs were dedicated to the fauna of prominent archaeological sites, especially in the German language literature where the processualist/postprocessualist divide was far less dramatic.

Diversification Period (1980s–present)

A revival came through advances in both archaeology and natural sciences on the one hand and in the international spread of zooarchaeology on the other. Due to immense diversification, only brief summaries of this on-going phase can be outlined here.

Ground-breaking research in stable isotopes (carbon, nitrogen, strontium, oxygen, sulfur, etc.) may be considered a spin-off from radiocarbon dating (van der Merwe 1982). Carbon and nitrogen isotopes became instrumental in assessing the type and proportion of plant to animal products in human and animal diets, refining reconstructions based on the traditional, morphological identification of animal remains. Radiogenic isotopes of strontium built into the mineral phase of the skeleton (Price et al. 2002) are of help in mapping regions where drinking water was consumed at various periods through an individual's life. Long-distance movements before or after death can thus be detected.

Complementary to the osteological evidence of meat consumption is the analysis of food residue preserved on ceramic sherds developed by Evershed et al. (1997).

The advent of ancient DNA studies has exposed the key relationship between heredity and environment, often treated superficially in conventional zooarchaeology. Wilhelm Johannsen introduced the term phenotype in 1911 to distinguish between an organism's inherited genotype and the effect of environment on its manifestation. In the absence of genetic information, however, zooarchaeologists attributed skeletal variability either to "superior breeding skills" (e.g., in Roman provinces) or to "environmental strain." While all experts *knew* that size and shape were a composite of heredity and environment, the emphasis shifted with the archaeological narrative. Ancient DNA was first recovered from a nineteenth-century museum specimen of the *quagga*, a South African wild horse extinct in 1883 (Higuchi et al. 1984). While DNA fragments are not always well preserved and expensive to extract, recently the analysis of mineralized residual collagen in archaeological bone using soft-ionization mass spectrometry (ZooMS: Zooarchaeology by Mass Spectrometry) has offered an affordable alternative in molecular species identification (Collins et al. 2010).

In response to postprocessual criticism, traditional zooarchaeology also started addressing new, culturally informed questions. Previously neglected aspects of social identity, gender, and agency began to be studied. Focus from production shifted to the more tangible aspects of consumption (household archaeology and feasting). These approaches gave a special inspiration to studies of bone manufacturing. While in the 1980s bone tools and ornaments began to be integrated with ordinary animal remains within the framework of raw material studies, the focus did not extend much beyond technological reconstruction and function. Recent discussions, however, incorporate key theoretical issues, re-connecting the study of manufactured animal remains with archaeology.

Zooarchaeological Data and Interpretations

Traditionally, hand-collected bones of large mammals have been studied. However, dry or wet-sieving is needed for the recovery of small vertebrates (e.g., rodents, birds, fish) and for unbiased anatomical recovery even of larger species. Especially fine methods are required in the study of minute insect and endoparasite remains.

The use of reference collections is advisable during identification. However, comparative materials are not always at hand in the case of extremely variable taxa (e.g., song birds) or are unavailable on-site in countries where exporting archaeological finds is illegal. In such cases osteological atlases (e.g., Schmid 1972) have been indispensable. Recently a number of on-line resources, including 3D imaging, have significantly broadened the range of comparisons.

In addition to taxonomic information, the skeletal part, as well as the age and sex of the animal need to be recorded whenever possible. Fragmentation and human modifications such as cut marks, traces of burning, or evidence of manufacturing should also be documented. All available standard measurements must be taken on each bone. Finally, precise stratigraphic information is required as no bone can be considered a "find" without proper archaeological context.

Once a database of individual finds is compiled, analysis begins with cross-tabulating the numbers of identifiable specimens (NISP) by animal species and skeletal part. These counts are, however, invariably biased by preservation. When bone weights are recorded, a similar summary will reveal the degree of fragmentation. In order to offset fragmentation bias, the minimum numbers of individuals may be estimated.

MNI is based on the most commonly found skeletal element of each species at a site. Simply put, finding three left boar tusks among ten pig bones would mean that at least three individuals were slaughtered. The use of MNI values has been hotly contested for decades as the way various authors calculate them strongly differ. Problems of interpretation also arise as minimum numbers vary depending on the way stratigraphic units are grouped for the calculation (aggregation effects; Grayson 1984). Moreover, MNI estimates are often taken at face value as "herds," forgetting that the calculation shows theoretical minima and some deposits characterized by these usually meager numbers had spanned centuries (NB the method developed by White in 1953 was aimed at calculating the dietary contribution of animals). Various refinements and redefinitions of MNI in zooarchaeology have not yet been successful in properly addressing these key problems.

Since the nineteenth-century biometry has been an essential tool used in taxonomic investigations in zoology. The comprehensive bone measurement manual by Jan Ulrich Duerst (1926) was simplified for zooarchaeological use by Angela von den Driesch (1976). Distinctions between the domestic form and its wild ancestor as well as secondary sexual dimorphism are often studied using measurements. A similar protocol for fish bones was published by Morales and Rosenlund (1979). Recently the development of geometric morphometrics (GMM; Bookstein 1991), a multivariate method of analyzing shape, has become important. This method can be profitably used in combination with ancient DNA information in recognizing genotype, the inherited component behind the external appearance of bones (phenotype).

Age and sex are manifested in some bones such as horn cores, teeth (e.g., boar tusks) and cock spurs. Measurements can also be used in sexing animal remains. Age data are often scrutinized in the wider context of hunting strategies and exploitation for secondary products in domesticates. Secondary exploitation means the extended use of live animals for renewable resources such as milk, wool, labor, manure, companionship, and prestige. While meat can be acquired by hunting, secondary exploitation relies on animal keeping. Ground-breaking ethnographic observations by Sebastian Payne (1973) have been widely used in establishing demographic curves demonstrating longevity in herds, usually associated with secondary products such as wool. The effect of culling young animals is often interpreted as a sign of dairy exploitation, although this phenomenon may be far more complex.

In zooarchaeology, reconstructions of kill-off patterns and putative herd structures are implicitly based on precarious MNI estimations, however, often disregarding distinctions between sheep and goat and the sex of the animal that cannot be recognized on the morphology of juvenile bone. This scarcity of detail, exacerbated by problems of bone preservation, makes the application of Payne's inventive method laden with cumulative bias beyond the control of zooarchaeologists. Spurious interpretations regarding "herd management strategies" abound when in fact one is dealing with humble food refuse reflecting the dietary contribution of animals in a certain time and place, and only indirectly related to herding. However, current discussion concerning the critical re-evaluation of the method (Vigne & Helmer 2007; Brochier 2012) and its integration with independent evidence from, for example, milk residue and dietary isotope analyses have opened new perspectives.

Current Issues

Given its increasing diversity, zooarchaeology contributes to several strands of ground-breaking archaeological research. The following examples illustrate only some of the developments in zooarchaeology 170 years after the first archaeozoological treatise by Steenstrup.

Domestication

As detailed in numerous additional entries in this volume, problems of domestication have traditionally dominated debate as a technological development of utmost importance. The first ever international conference on archaeozoology was devoted to domestication research and the history of domestic animals (Matolcsi 1973). Questions concerning the places and times of first domestication remain to be resolved.

Just as large series of accelerator mass spectrometry (AMS) dating have become instrumental in fine-tuning conventional radiocarbon chronologies (frequently using animal remains), studies of ancient DNA, food residue, and dietary stable isotopes have revolutionized domestication research. Put in a proper chronological framework, genetic studies began to offer reliable data for mapping domestication trends for the first time (Harris 1996). By the beginning of the new millennium, complex ancestral lineages have been outlined for most domesticates (e.g., Larson et al. 2007; Pedrosa et al. 2007).

Evidence of Early Neolithic dairy exploitation of Bovids in Europe was found through residue analyses (e.g., Craig et al. 2005). Remains of mare's milk at the Chalcolithic site of Botai in Kazakhstan furnished long-awaited key evidence that the numerous horses killed at the settlement were already domesticated, as milking wild horses would have been unlikely (Outram et al. 2009).

Fauna history

Although prone to increasing "noise" created by past human activity, zooarchaeological finds can contribute to studying fauna history and zoogeography. For example, a trend of the northwest to southeast extinction of European lions may be traced across the Balkans between the Early Neolithic (ca. sixth millennium BC) and the Early Iron Age (ca. first millennium BC) in the Pontic region. Considering that all lion remains marked in Fig. 3

Zooarchaeology, Fig. 3 The extinction of European lions in the Balkans in estimated chronological order. Legend: 1 Karanovo II, Early Neolithic, Bulgaria; 2 Dikili Tash, Neolithic, Greece; 3 Zengővárkony, Late Neolithic, Hungary; 4 Tolna–Mözs, Copper Age/ Furchenstich culture, Hungary; 5 Hódmezővásárhely–Kopáncs-Olasz tanya I.; 6 Tiszaföldvár–Téglagyár, Copper Age, Hungary; 7 Gyöngyöshalász–Encspuszta, Copper Age, Hungary; 8 Tiszalúc–Sarkad, Copper Age, Hungary; 9 Hârșova, Late Copper Age/ Cernavoda level, Romania; 10 Mayaki, Copper Age, Ukraine; 11 Bolgrad, Copper Age, Ukraine; 12 Goljamo Delčevo, Copper Age, Bulgaria; 13 Slatino, Copper Age, Macedonia; 14 Devetashka Cave, Copper Age, Bulgaria; 15 Sozopol, Copper Age, Bulgaria; 16 Durankulak, Copper Age and Late Bronze Age, Bulgaria; 17 Tiryns, Late Bronze Age, Greece;18 Keos, Late Bronze Age, Greece; 19 Delphi, Late Bronze Age-Iron Age, Greece; 20 Kastanas, Late Bronze Age-Iron Age, Greece; 21 Kalapodi, Iron Age, Greece; 22 Tira, Early Iron Age, Ukraine; 23 Ol'biya, Early Iron Age, Ukraine; 24 Berezan, Early Iron Age, Ukraine; 25 Chernomorka I, Early Iron Age, Ukraine; 26 Chernovaty, Early Iron Age, Ukraine

were deposited by humans, the zoogeographical reliability of individual finds can be critically appraised on the basis of skeletal part distributions: teeth may have been widely circulated prestige goods/amulets, while bones of the feet could be left in high status imported lion skins. However, numbers of ordinary bones representing lion carcasses rather than these prestigious parts were also recovered to substantiate the main zoogeographical tendency outlined in Fig. 3. A concentration of Early Iron Age finds from the Western Pontic Coast may represent live imports to Hellenistic colonies from outside Europe, although this hypothesis (based on

subsequent Roman and Byzantine analogies) remains to be supported by DNA and/or strontium isotope analyses.

Events in fauna history are inseparable from environmental change. Bones of large game of diagnostic value, however, are found relatively rarely. Small organisms with faster reproduction rates have been particularly useful in reconstructing environmental history. Masses of marine fish remains from Danish coastal sites representing the warm Atlantic period (7th–4th millennium BC) could be profitably used to model future changes in combination with modern fisheries records (Enghoff et al. 2007). The authors conclude that major changes to fish stocks will be inevitable. Although economically important cod populations can potentially be maintained in waters near Denmark, the vulnerability to increasing water temperatures will increase fish mortalities.

Taphonomy

Taphonomy is the critical appraisal of postmortem processes that turn animal carcasses into "finds." This important concept adopted by zooarchaeologists by some 40 years ago had developed in paleontology (Efremov 1940). Until the 1960s, most archaeozoologists had typically explained assemblage variation by ancient human behavior, often disregarding effects of differential preservation and methods of recovery. From an archaeological point of view, predepositional (biostratinomic) modifications to animal remains are of special interest. In contrast to paleontology, ancient human activity had a key role to play in shaping zooarchaeological assemblages. Culturally characteristic ancient modes of butchering and cooking expose bones to further deterioration by natural agents in the deposit. Moreover, studies of animal pathology can be most reliably carried out on animals that were interred largely intact as unfit for human nutrition. Frequently buried alongside humans, horses and dogs may be viewed in a broader cultural context (e.g., in relation to the gender, age, and status of the deceased human) in addition to their anatomical integrity preserved under favorable taphonomic circumstances (Fig. 4).

Zooarchaeology, Fig. 4 Fifteen pathologically fused thoracic and lumbar vertebrae from a ca. 14 years old stallion from the Late Avar Period (eighth–ninth century) cemetery of Tiszafüred–Majoros, Hungary. For years this animal must have been decapacitated and unfit for riding, but it had evidently been taken care of and was finally interred within a human cemetery

Complex Cultural Interpretations

It has been recognized that beyond food production, patterning in bone assemblages may be related to subtle aspects of animal use in social self-representation, exchange, and communal consumption (Marciniak 2005; Russell 2012). Taphonomically informed analyses of animal remains have gained new momentum within another trend of investigating the "biography" of artifacts in archaeology. High prestige items in particular, such as the canine teeth preserved in

the carefully sawn-off skull fragment of a medieval leopard found in Hungary (Fig. 5), embody inseparable overlaying aspects of zoological, taphonomic, technical, and culture historical information. Large predators especially can be exploited in a number of ways depending on their availability, perceived value, and symbolic meaning. Each of these forms is expressed in different degrees of skeletal representation ranging from complete through scattered to carefully selected, the latter cases usually standing for the complete beast symbolically. The biography of such objects parallels their taphonomic history, composed of decisions made from hunting through the degrees of carcass partitioning prior to selecting special parts depending on intended use. For high status items, careful, decorative manufacturing adds to the value of the objects. Finally, such artifacts may be deposited under special circumstances further improving their state of preservation and chances of recovery (Fig. 6). Prestige goods made from rare animals may end up in burials or in well-investigated high status proveniences.

Zooarchaeology, Fig. 5 Sawn-off muzzle region of a large leopard skull with upper canine teeth worked into a high status decorative item from the fourteenth century town of Segesd–Pékóföld, Hungary. The object may have belonged to an exotic leopard skin such as those once worn by members of the Teutonic order

International Perspectives

Even though archaeological cultures cross-cut national borders, their geographical and chronological extent is limited. Thanks to the universal use of animals and the fact that the animal skeleton is far more standardized than most archaeological objects, zooarchaeology is an

Zooarchaeology, Fig. 6 Taphonomic aspects determining the biography of large predator remains in archaeological contexts. Perceptions and values of animals vary depending on their availability and uses in various cultural settings as reflected in zooarchaeological finds

emphatically international discipline. Its principles and main methods are globally applicable with little or no variation between archaeological periods. The "integration period" in zooarchaeology not only meant increasing integration with archaeology and other disciplines, it also brought about the recognition that zooarchaeologists worldwide had shared academic interests. In 1971, the International Council for Archaeozoology (ICAZ) was created in order to foster communication between practitioners in this narrow field. Europe was politically divided at the time, but this important channel of communication between East and West functioned very well, also involving scholars from North America. By the twenty-first century ICAZ musters a global membership.

While developing countries served as areas to be explored by archaeological expeditions from the "Western World" for over a century, increasing numbers of local archaeozoologists began working in these areas on behalf of their own heritage management. Zooarchaeology has a long tradition in Russia and other republics of the former Soviet Union. The discipline is also important in China, but little has been known abroad about work in these countries, largely due the limited international dissemination of results rooted in linguistic isolation. From this point of view, Latin America has been in a more advantageous position as respectable research traditions in countries such as Argentina and Mexico have been more directly linked to both Europe and North America, providing channels of publicity beyond the region.

Future Directions

Since its rise in the mid-nineteenth century, zooarchaeology has reflected shifts in the broader ideological environment, largely mediated through developments in archaeology itself. The evolution of both political and scientific thought contributed to the diversification of this subject in its academic scope, geographical focus, and interdisciplinary integration. Traditional methods of identifying and inventorying animal remains from archaeological sites form a basic part of any respectable policy in heritage management. Additional locally available analytical methods and the redistribution of scientific capacity in leading research institutions through the international network of zooarchaeologists will determine the new directions and pace of development in our discipline. Targeted use of increasingly available chemical identification (such as ZooMS; Buckley et al. 2010), complementing traditional morphometric analysis, already began to have an impact on how zooarchaeology is done in the twenty-first century.

Zooarchaeology by Mass Spectrometry (ZooMS)

Nienke L. van Doorn
BioArCh, University of York, York, UK

Brief Definition of the Topic

Zooarchaeology by mass spectrometry (usually abbreviated as ZooMS) is a minimally destructive method to determine animal origin by peptide fingerprinting for (mineralized) collagenous materials.

Mass spectrometry (MS) of proteins has been made possible due to the introduction of "soft" ionization methods, most notably MALDI (matrix-assisted laser desorption/ionization) and ESI (electrospray ionization) MS. MALDI achieves ionization of peptides through proton transfer via a solid matrix, where electrospray ionization can be attained directly from the liquid phase. These ionization methods allow molecules to not be degenerated during measurement. Where "harder" ionization would break down a protein in random fragments that are difficult to predict, proteins are instead digested by enzymes into peptides. Restrictive enzymes cut at specific sites (lysine and arginine for trypsin, the most common enzyme used for this purpose), creating consistent and predictable fragments. The resulting peptides can therefore be compared to theoretical fragments based on in silico digestions of known protein sequences.

ZooMS uses MALDI ionization to investigate materials such as bone extracts as these are relatively simple aqueous solutions, containing almost exclusively collagen type I. Collagen type I, the main organic constituent of bone, teeth, antler, and skin (leather and parchment), has a helical structure and consists of three fibrils: two α1 chains and one α2. Some fish collagens also contain a subunit α3 in lieu of one α1 chain. Although collagen is highly conserved through closely related taxa, especially within COLI-α1, there are minor – though significant – changes in primary sequence between genera and in some cases species. The changes in primary sequence cause differences in mass, ultimately producing a fingerprint of masses that may be (partially) characteristic for the animal of origin. Therefore, identification is dependent on the extent of evolutionary divergence (typically to the level of genera). For example, using ZooMS, sheep and goat can be distinguished primarily through a single peptide showing a mass difference between the two species (Buckley et al. 2010). Fingerprints are matched to either theoretical data based on in silico digestions of sequences obtained through cDNA libraries or comparison to practical data obtained through ZooMS analysis of known standards. In-house collagen databases are currently expanded to animal species other than mammals, including fish (Richter et al. 2011) and birds. Alternatively, indexed peptides of thoroughly investigated taxa can be used to determine animal origin.

Current generations of (MALDI) spectrometers can measure peptides at levels of a

femtomole. Although this risks detecting contaminating substances (such as cellular keratins or autocleavage products of trypsin), the source material does not require amplification, and the extract is measured "as it is obtained." Common contaminants are well documented and do not necessarily interfere with a fingerprint obtained from collagen.

With this high sensitivity, a partial extraction in a mild buffer is often sufficient to obtain reliable and repeatable results, both for animal origin identification and thermal age estimations (see below), especially for samples that are well preserved and have been protected from water flux or modern material such as bone particles in meat and bone meal. In some situations, samples are decalcified prior to buffer extraction. This overall yields a higher concentration of collagen; however, it is permanently destructive to the sampled material. A buffer-only extraction will not significantly damage well-preserved mineralized artifacts.

Peptide fingerprinting (and by extension ZooMS) is a fast- and low-cost method: hundreds of samples can be processed in a day at a cost of <15! per sample.

Deamidation (the loss of an amino group, e.g., glutamine, is transformed to glutamic acid) is a very common nonenzymatic posttranslational modification in proteins and is commonly associated with ageing of tissues. This process continues postmortem and can therefore indicate the amount of damage proteinaceous substances have been exposed to. Without altering the method as described above, the amount of overall deamidation between several glutamine sites in bone collagen can be estimated (Wilson et al. 2012), and this has been shown to correlate well with thermal age but poorly with common diagenetic parameters. ZooMS can therefore not only yield animal origin but also give an indication of (thermal) damage without necessarily damaging the originating material. A definite link between ZooMS success and degree of deamidation and DNA amplification has not been clearly established. However, a buffer-only extraction does not prevent successful DNA extraction from the exact same samples.

ZooMS is applicable to any venture that involves minimal sampling of collagen-containing material. Applications of ZooMS include investigation of animal feeds or detecting counterfeit leathers. In an archaeological context, advantages of ZooMS range from investigating rare or precious artifacts, morphologically indistinct bones, or very small (<250 μm) fragments that are otherwise problematic to identify. The high-throughput setup of ZooMS allows for cost-effective screening of samples prior to more expensive or destructive analyses, including aDNA. Buffer-only extraction only leaches partial collagen and has been shown to be nondestructive even to microscopic features, such as toolmarks, and allow for repeat or follow-up analyses on the same material. The estimation of thermal age through glutamine deamidation may aid discrimination of bone samples from multilayered sites.

New applications and optimization of both method and database are continuously in development, making ZooMS, along with its currently established advantages, an important tool for zooarchaeologists to consider more routinely in the future.

Zooarchaeology: Methods of Collecting Age and Sex Data

Deborah Ruscillo
Department of Anthropology, Washington University in St. Louis, St. Louis, MO, USA

Introduction and Definition

Zooarchaeology has taken great strides since the early 1900s when a zoologist or veterinarian might occasionally have been consulted to examine animal bones recovered from archaeological excavations, if the context in question was believed to be especially important. Faunal reports from that era were often simply lists of species present: specific elements may or may not have been listed, and the age and sex of individuals represented were certainly not included. Having consulted the zoologist at all was a big enough step in archaeological scientific inquiry at the time. Most excavations before 1960 did not even bother collecting animal remains, and it was not until the 1970s when the processualist movement took hold in archaeology that excavators began consistently to consider bones a valuable source of environmental and anthropological information. However, in order to obtain that information, more data was needed from the animal remains themselves.

Understanding past lifeways through faunal remains is contingent on the amount of information one can extract from those remains. Determining the age and/or sex of animals slaughtered for daily food requirements or ritual purposes can aid in the reconstruction of herding strategies or ceremonial procedures, respectively. For example, identifying a predominantly older female population among sheep remains can suggest a secondary product strategy. In this instance, ageing and sexing information from animal remains is crucial to the interpretation of culturally deposited bone.

The evolution of the study of animal bones was facilitated by adopting methodologies pioneered originally for the study of human bones. Thus, systematic studies of dental eruption and attrition, and epiphyseal fusion of postcranial bones using modern specimens enabled the definition of stages of growth and development which could then be applied to archaeological specimens. These techniques were proven to be effective for the study of archaeological human remains and were then applied to common domesticates. As more techniques developed in the study of humans, so too did the application of similar methods to animal bones. Metrical and morphological studies proliferated, especially for dental analyses. More recently, technological innovations in morphometric and microscopic analyses have been used to age and sex animal bones, as have genetic and histological methods. These techniques are outlined below in simple terms, from the most basic to the most advanced available today. This entry is not meant to present a summary of every study produced on ageing and sexing – such a feat would require a volume unto itself. Rather, it describes many of the more common methods available for distinguishing age and sex.

To date, there are three major volumes that compile methods for ageing and sexing of archaeological animal bones. These are Ruscillo

(2006a), Pike-Tay (2001), and Wilson et al. (1982). Countless articles in journals and edited volumes have also been written, each presenting its own unique application of known methods of ageing and/or sexing or presenting new methods for applicability to animal bones.

Key Issues and Current Debates

Ageing Methods

Cortical Bone Texture

Perhaps the most basic method of determining age is to inspect the texture of cortical bone. Fetal and juvenile specimens exhibit rough developing cortex which becomes smoother with age. This texture difference is due to extracellular modifications of collagen as well as other developmental processes involving the mineralization of bone. Histological studies show microscopic differences in the structure of juvenile and adult bone tissue, but more useful to the bone analyst are the visual and tactile differences of the bone cortex which will immediately distinguish younger from older individuals. Although not always useful for suggesting precise ages, this method can be used in a bone assemblage to establish the presence of juvenile and immature specimens. Figure 1 shows the cortical differences between juvenile, immature, and adult long bones.

The juvenile bone (Fig. 1a) has a rough cortex, similar in texture to fine sandpaper. The younger the juvenile individual is, the finer the granularity. Fetal bones are smaller and less developed and have a very fine granular texture. Fetal specimens are often difficult to distinguish from neonatal individuals and can be described as "perinatal" i.e., having died close to the date of birth, either before (prenatal) or after (postnatal).

The immature specimen (Fig. 1b) has residual rough cortex around the epiphyseal joint, especially towards the ends of the bone diaphysis (shaft). This roughness decreases with age as the cartilage between the epiphysis and diaphysis ossifies. By maturity (Fig. 1c), the cortex is smooth with well-defined muscle attachments.

Zooarchaeology: Methods of Collecting Age and Sex Data, Fig. 1 Differences in cortical bone texture in (**a**) juvenile bone, (**b**) immature bone, and (**c**) adult bone. (Image by the author, with thanks to Lucretia Kelly for the specimens)

A good synopsis for identifying fetal bones in archaeological contexts is Prummel (1987). For a useful reference work on the ageing of fetal bones, see Habermehl (1975).

Epiphyseal Fusion

Analysis of epiphyseal fusion is the most common age determination technique used for postcranial bones. The fusion of bone epiphyses to the adjoining diaphysis occurs in regular stages during development and is fairly predictable with age, thus representing a good age indicator.

Silver's reference work *The Ageing of Domestic Animals* (1969) greatly aided faunal analysts when zooarchaeology was still in its infancy. Not only did Silver gather information from older veterinary and zoological studies on tooth eruption from nine major domesticates (horse, ass, cattle, sheep, goat, pig, dog, cat, and camel), but he also recorded the ages of epiphyseal fusion for almost all postcranial elements. Despite some problems, this work is still consulted for good estimates of age based on the state of epiphyseal fusion of specific bone ends and also for dental eruption timings (see below).

Many studies following Silver have attempted further to define ages from epiphyseal states while also considering influences such as castration, breeding, and environmental factors (e.g., see

Davis 2000 for the delayed epiphyseal fusion of bones due to castration in a population of Shetland sheep). Problems with this method arise when trying to determine ages over four years for ungulates and over a year for smaller mammals such as canids and felids. After the complete fusion of long bones, ageing individuals is impossible without incorporating some other method, such as dental attrition which continues throughout life.

Since the fusion states of individual specimens typically only provide age estimates of the form "younger than *x*" or "older than *y*," moving from this to an estimate of population structure or kill-off pattern is not straightforward. The usual approach is to combine elements into a number of groups, from the earliest-fusing to the latest-fusing (e.g., Zeder 2006), and to calculate the percent of specimens that are fused within each of these. One naturally expects to see a drop-off in "percentage fused" as one moves towards the later-fusing groups, but the rate and position of this drop-off can indicate kill-off structure (Fig. 2).

Zooarchaeology: Methods of Collecting Age and Sex Data, Fig. 2 Epiphyseal fusion drop-off curve for sheep at Halaf period Fıstıklı Höyük, Turkey. Data points represent the percentage of specimens fused or fusing in each of five sequential fusion groups (as defined by Zeder 2006). Numbers in brackets are the sample sizes for each group. (Image from David Orton, used with permission)

Tooth Eruption

The most commonly used age determination methods involve some form of dental analysis, partly due to the high preservation rate of teeth and mandibles. As with humans, other mammals have fairly predictable ages of tooth eruption and development. Mandible and maxilla fragments with teeth still intact can thus often offer fairly accurate estimates of age-at-death, especially for complete mandibles or maxillae and for individuals under 48 months of age, the time when most medium-large mammals have completed eruption of all teeth.

If the permanent dentition is fully erupted, other methods of ageing teeth can be adopted, such as measurements of dental attrition or cementum annuli counts (see below). Studies such as Deniz and Payne (1982) on goats and Jones (2006) on sheep have developed methods of ageing which consider both eruption stages and tooth wear to produce a complete mortality profile of a population. Zeder (2006) considered both tooth eruption and wear along with long bone fusion to further refine age determination accuracy in caprids. Similar work has been performed with wild and domesticated pigs by Bull and Payne (1982).

Tooth Wear and Dental Attrition

Much work has been performed on recording the rate at which dentition wears for different species. Theoretically, dental attrition progresses at a predictable rate so that wear can be measured within an accuracy of months to determine the age at death of an individual. Factors which affect the rate at which attrition occurs include feed, captivity, and environmental conditions for grazing. Sex and side of dentition do not generally seem to significantly affect attrition.

Methods usually involve observing and recording the wear on the occlusal surfaces of a row of teeth. Diagrams using standardized coding, such as those shown in Fig. 3, can be drawn to show patterns by indicating the level of wear of the occlusal enamel, cementum, and dentine of a specimen (after Grant 1982; see also Payne 1973). Theoretically, individual permanent teeth can be aged in this

Zooarchaeology: Methods of Collecting Age and Sex Data, Fig. 3 Dental attrition on a cattle mandible from Vindolanda (V07 69A 18174) with corresponding diagram of tooth wear patterns. (Images by Deb Bennett, used with permission of the Vindolanda Trust)

Zooarchaeology: Methods of Collecting Age and Sex Data, Fig. 4 Cementum annuli as seen under a microscope with dye for contrast (Image copyright Gary Matson/Matson's Lab, used with permission)

manner if given a dataset from known age/wear individuals, but usually this method is performed on complete or partially complete mandibles.

Tooth Crown Heights

Examining tooth crown heights is another method for gauging attrition. Typically, the distance between the occlusal surface and the line separating the enamel of the crown from the dentine of the root is measured for each relevant tooth on the buccal side (outlined in Klein and Cruz-Uribe 1984: 46–47). These measurements can then be analyzed in various ways, including Klein's and Cruz-Uribe's own Quadratic Crown Height Method (QCHM) which predicts age based on eruption age, unworn height, and an estimate of the age at which the crown would be completely worn down. Alternatively, linear and quadratic regressions have been performed using measurements on specimens of known age. This technique has been applied to cervids, bovids, and equids.

Cementum Annuli Counts

Tooth cementum is laid down continuously, but seasonal differences in deposition rate result in growth banding analogous to tree rings. When a tooth is thin-sectioned and stained for greater visibility, the rings (annuli) can be counted under a microscope and used to estimate age. Figure 4 shows dark annuli that have been deposited in the winter months, while the larger lighter-stained cementum represents the growth period in the spring and summer. Most wild animals can be aged this way, especially those from northerly latitudes where seasonal temperatures are more distinct. Domesticated animals and species in less seasonal climates may exhibit less characteristic seasonal growth patterns in dental cementum because there are less distinct differential feeding and growth periods.

Not only can this method be used to age animals at death, but the season in which the animal died can also be postulated.

Sexing Methods

The number of diagnostic features in a skeleton that indicate the sex of an individual differs from species to species. The predominant difference between male and female individuals is size dimorphism; males tend to be larger than females. Some species like pigs and deer are highly dimorphic, while many smaller species, such as hare, are less so. Thus, osteometric data can be used to estimate sex ratios for many species if the sample size is large enough. More reliable for identifying males from females, however, is the recognition

of primary, secondary, and tertiary sexual characteristics. These are outlined below.

Primary Sexual Characteristics

Primary sexual characteristics are, of course, the reproductive organs. These features are useful for sexing individuals while they are alive, but after death reproductive organs generally do not survive in the archaeological record. The baculum or penis bone, however, can preserve in certain conditions. Carnivores such as procyonids, mustelids, canids, felids, ursids, and pinnipeds have bacula. Occasionally, some of these species may have a female equivalent bone in their clitoris, the *os clitoridis* or baubellum, but this element is often absent or cartilaginous and cannot be predictably found in female individuals archaeologically.

The presence of a baculum in an archaeological sample or in a burial of a complete skeleton signifies a male individual, but not finding a baculum does not necessarily mean that males are absent. Some bacula are small and fragile and do not preserve well. Alternately, finding a baculum does not mean that females do not exist in a sample. The presence of a baculum is most useful for sexing when excavating whole skeletons. Canids, in particular, are sexed in this manner because many cultures bury companion animals purposefully.

Secondary Sexual Characteristics

Secondary sexual characteristics include features that males possess which females do not. These commonly include horns, antlers, tusks, large canines, and spurs. The identification of sex based on these secondary features is not a relative value like ageing data. Instead, it is based on a present or absent classification as with bacula. For example, if large canines from a wild boar are present, the identification of the individual as male is certain. A secondary trait that is relative is body size; mature males are larger than females in most mammals. A comparison of size data within a faunal sample can often distinguish size dimorphism.

Headgear Horns and especially antlers are good indicators of male individuals. If a frontal bone is found with pedicles from antlers, identifying the individual as male is certain (with the exception of caribou/reindeer). Caution must be used when interpreting sex based on pieces of antler – finding antler is not always evidence that male deer was hunted. Male deer molt their antlers after the annual rut in the late autumn or early winter, and these may be collected by humans. Both sexes of caribou produce antlers. The males, like most cervids, will shed their antlers after the rut, while females will shed theirs during the winter months unless they are pregnant, in which case they will retain their antlers until the spring.

Horns differ from antlers in that the horncores actually form part of the cranium; they are made of bone and are not shed. Many species exhibit horns on male individuals only, but some bovids have produced breeds where both males and females have horns. Work on distinguishing between the sexes by identifying horncore morphology has been performed so that the horns themselves can be sex indicators (Armitage and Clutton-Brock 1976, although see Sykes and Symmons 2007). Studies have shown that castrating male individuals early in life will affect the development of the horn cores. Thus, horncore morphology may also be useful in identifying castrates in a bone sample (Fig. 5).

Canine Morphology Another potentially diagnostic difference between male and female animals

Zooarchaeology: Methods of Collecting Age and Sex Data, Fig. 5 Horn-core differences in male, female, and wether sheep individuals as determined from radiographs. (After Clutton-Brock et al. 1990)

is canine size. This is true of many species, including suids, equids, moschids, hippopotamids, and elephantids, among others. With the exception of equids and moschids, male tusks grow perpetually throughout life; an old adult wild boar can have tusks of a considerable size. In equids and moschids, canine teeth are much more prominent in the male individuals. Only 25% of female horses produce canines, and these are usually small in size. For felids and canids, canines seem to be proportionate with size. Females, being diminutive in stature, will naturally have smaller canines. It is difficult, however, with domesticated dogs and cats to use canines as sex indicators because manipulated breeding has produced great size variety which plays a large role in determining the overall stature of male and female individuals and their sexually dimorphic characters.

Size Dimorphism or Trimorphism Size dimorphism is the most inclusive of all the sexually dimorphic differences in animals. Almost all mammals with the exception of the spotted hyena and the blue whale exhibit larger male stature and/or female gracility. This size dimorphism is measurable using standardized bone measurements, the collection and manipulation of which is known as biometry or more specifically *osteometrics*.

If the bone sample size is large enough, one can plot bone sizes (e.g., length versus width of any complete bone) to reveal size dimorphism in a population. Usually, there will be great overlap between the sexes, especially if there are wild and domestic populations or multiple domestic breeds present at the site but also because adult females and immature males are often similar in size. The challenge when interpreting osteometric data is that male animals are often culled from the population before maturity is reached, while females are often kept until they are too old to produce offspring or secondary products like milk. Males that are kept for meat, wool, or labor will often be castrated, further complicating the interpretation of the data. Castrated mature males are still larger than females, but their economic contribution to the herd has been altered: males can be used as studs or for sport (e.g., bullfighting), while castrates are kept either for meat (as in pigs and bovids), for wool (e.g., sheep), or for labor (as in cattle or equids). One cannot usually tell if the larger individuals in a site population are male or castrated individuals from size alone without also examining morphological differences using morphometrics, discussed below.

Bones that preserve well in the archaeological record and for which osteometrics have proven particularly useful for distinguishing between males/castrates and females include the metapodials, especially among bovids.

Birds Birds also exhibit secondary sexual characteristics in the form of spurs (males) and calcium deposits in the medullary cavity (females). Plumage is also a secondary trait, males often displaying more flamboyant colors and longer tail feathers, but these features rarely survive in the archaeological record.

Zooarchaeology: Methods of Collecting Age and Sex Data, Fig. 6 Sexual dimorphic characters of *Gallus*, (**a**) medullary bone from a hen, and (**b**) a spur on a tarsometatarsus of a cock. (Image copyright Lena Strid, used with permission)

Medullary bone is deposited commonly in the leg bones of female birds (femur, tibiotarsus, and/or tarsometatarsus) during egg production. Figure 6a shows a layer of mineral deposits in a tarsometatarsus of a hen. The medullary bone acts as a repository for the storage of calcium required for eggshell development. The medullary cavity can have a significant amount of mineral deposition, or the mineral stores can be represented by a fine bony web within the cavity. The extent to which the medullary bone is laid down is dependent on the species of bird, its age, its egg productivity, the mineral content in its diet, and other environmental factors. In order to examine this trait, however, one would need either to break the bones open or to use radiographs (O'Connor and O'Connor 2005). Medullary bone can also be considered a tertiary sexual character, for it arises after the sexual maturity of the animal and not during puberty.

Male spurs are more obvious on the tarsometatarsus on most adult galliform birds (Fig. 6b). This family includes turkeys, chickens, quails, pheasants, and peacocks. These spurs are used in mate and territory competitions and are useful indicators of sex.

Tertiary Sexual Characteristics

Tertiary sexual characters differ from secondary traits in that they arise during maturity and not as a direct result of sex hormones during puberty. Tertiary traits develop as a result of sex-specific behaviors (i.e., pelvic changes due to pregnancy and birth) or in support of secondary traits (i.e., atlas changes due to muscle development for headgear support). These affected bones are found in different places in the body but mainly involve the neck, the pelvis, and the lower extremities.

Pelvic Morphology The easiest and most common method for identifying sex through skeletal morphology is by examining the shape of the pubis. For ruminants, if the pubis is oval or round in section, it is a male individual. If the pubis is thin and slightly twisted, it is female (Fig. 7). Caution should be taken when examining female pubes – a male castrated within the first few days of life will develop a thinner pubis as well; the pubis of the castrated individual will resemble that of a female who has not yet reproduced. The absence of androgens during the early development of males will default the female morphology.

Zooarchaeology: Methods of Collecting Age and Sex Data, Fig. 7 Bovid pubes of a male and female

The shape of the obturator foramen, the space between the acetabulum, ischium, and ilium, can also be diagnostic of sex for ruminants. The female foramen is symmetrical and when traced resembles the shape of an avocado pit. The male foramen when traced is less symmetrical, bulging on one side compared to the other (see images in Ruscillo 2003). The foramen of a castrated individual interestingly resembles that of a male, probably due to its equitable size. Therefore, if one finds a complete innominate of a ruminant that has the pubis resembling that of a female and an obturator foramen of a male, then the identification of a castrated individual is likely.

A method for distinguishing sex in suids specifically is by measuring the height of the medial border of the acetabulum. Males have a higher medial wall than females – the female pubis is thin and the medial wall by association is also gracile (Greenfield 2006).

Mean Shape Method *Morphometrics* is a branch of mathematics which examines the metrical and statistical properties of shapes and shape changes of objects. Using techniques such as elliptic Fourier analysis (EFA) or eigenshape analysis, for example, bone morphology can be compared between the sexes in quantifiable terms. These techniques are particularly useful for

Zooarchaeology: Methods of Collecting Age and Sex Data, Fig. 8 Mean shapes of sheep atlases for (**a**) male, (**b**) female, and (**c**) wether. (From Ruscillo 2003)

examining tertiary sexual characteristics which are not immediately visible to the eye.

Ruscillo (2003) explores tertiary sexual characteristics using what she has called the "Mean Shape Method." By digitally outlining profiles of selected bone elements using a statistically sound number of specimens of known sex, eigenshape analysis can produce an average shape for each element by sex. Profiles were obtained by the use of profile gauges. These mean shapes can then be compared to the shapes of the archaeological specimens to determine the sex of the individual. The method was fruitful for cervids and bovids and indicated several bones that were sexually dimorphic. The transverse processes of the atlas were significantly dimorphic for both families of animals. Figure 8 shows the mean shapes of sheep atlases produced after scanning over 30 individuals of each sex including males, females, and wethers (castrated males).

Male and female bovids and cervids showed significant differences between shapes of the glenoid process (the articular part of the scapula) and the astragalus. For sheep, the transverse processes of the atlas, the astragalus, and the obturator foramen each showed a third shape corresponding to wethers. In general, the mean wether bone shapes are characterized as having the morphology of females with the size of males. Presumably, similar shapes would be expected of castrated goats, cattle, and cervids.

Table Test Sexing canid remains can be difficult unless a whole skeleton is present with a baculum. Isolated bones of canids can be problematical to sex because millennia of breeding the species have produced highly variable sizes and even bone shapes. However, a complete mature canid humerus can help suggest the sex of the animal with 85% accuracy. The "Table Test" is described by Ruscillo (2006b) and is fairly simple. The complete humerus is placed on its anteroventral side on a level surface. If the humerus falls over to one side, then it is likely a male individual; if it rests stably on its anteroventral side, then it is more likely to be a female specimen, though several male humeri were stable as well in individuals which were lap animals and did not exercise "normal" male behaviors. These individuals may have been castrated as well. The morphological difference being measured by this simple test is the size of the deltoid tuberosity which is significantly more developed in most male individuals because of the more robust deltoid muscle.

Future Directions

Much work has been done in the past 60 years to identify useful methods of ageing and sexing animal bones in the field and in the laboratory. There is still much to do, however. With advancements in technology, future work in ageing and sexing will no doubt involve more microscopic, chemical, and molecular analytical methods, as these become more accessible and affordable.

Osteohistology

Osteohistology is defined as the study of the microscopic structure, chemical composition, and function of bone. The stage of structural development of bone can be observed and recorded by viewing cross sections of bone under the microscope. The patterns of lamellar bone, osteons, resorption lacunae, and Haversian canals correspond to different ages. There are six primary stages of long bone structure in cross section (shown in Dammers 2006: 23; Fig. 8). With a detailed study of the bone structure of each taxon, age profiles can be recorded and used to age archaeological specimens. Many of these studies have yet to be done for specific taxa, but an overview of how this method can be applied to different species is explained in Dammers (2006). The development stages and patterns of bone structure are also distinctive of sex. Future work in this area is likely to prove invaluable.

Imaging

Medical imaging and 3D modeling technologies may be used to refine morphometric analysis for distinguishing between the sexes. Magnetic resonance imaging (MRI) technologies have, as yet, seen limited use with archaeological animal bone. Although radiography is currently preferred for inquiries related to bone, the image produced by MRI is superior for reproducing any object accurately in three dimensions, recording morphological and even histological information. With further refinement, minute histological details of bone structure may be more readily identified and accurate ageing assessed from bone samples.

There are many programs which have enabled the 3D imaging of objects. These programs replicate the specimen under examination by plotting coordinates on three planes. By comparing the location of a specific point or group of points plotted on the surfaces of an object, the principle components of shape can be measured and contrasted. Eigenshape analysis has already been used in comparing the eigensurface on paleontological species (MacLeod and Krieger 2007). This kind of technology will be especially useful for comparing sexual dimorphic differences in any species.

DNA and Molecular Studies

Every year strides in genetic technology are made, and improvements in cost and reliability are starting to make molecular sexing a viable option in archaeology. Genetic studies based on polymerase chain reaction (PCR) are already being implemented in projects involving various aspects of the origins of domesticated species.

In a study by Telldahl et al. (2012), for example, sex classifications based on measurements of cattle metapodia are corroborated by molecular studies. A sample of archaeological individuals was sexed using both conventional morphometric criteria and genetic analysis, and the results compared to establish the accuracy of the former. No doubt as DNA analysis becomes more mainstream and affordable, sex determination from bone remains will become easier and more accurate.

The future of ageing and sexing methods in zooarchaeology will likely be imaging and biomolecule based. New techniques will give rise to more accurate and more frequent identifications of age and sex, permitting creation of mortality profiles for animal populations from communities in the past. This should in turn give rise to a clearer picture of economics, trade, ritual, and daily lifeways of ancient peoples.

Zvelebil, Marek

Peter Rowley-Conwy
Department of Archaeology, Durham University, Durham, UK

Basic Biographical Information

Marek Zvelebil (1952–2011) was born in Prague, capital of the then-communist country of Czechoslovakia. He relocated to the west in his teens with the rest of his family and studied at Sheffield and Cambridge. He spent 30 years as part of the faculty in Sheffield until his death in 2011.

Marek's interests were highly diverse. His mastery of eastern European languages enabled him to study shamanism among Siberian hunter-gatherers; he collaborated with his father, the eminent linguist Professor Kamil Zvelebil of Leiden University, in disputing the Early Neolithic origins of the Indo-European language group; he collaborated in fieldwork projects in Ireland and the Outer Hebrides; and after the fall of communism, he started to work in the Czech Republic. But Marek is mainly known for his work on the hunter-gatherers of the Baltic region and their part in the transition to agriculture. His Ph.D. was on this topic. His study visits to Finland were always via ferry and car – not by air – for fear that a flight approaching a fog-bound Helsinki

Zvelebil, Marek, Fig. 1 Chart showing the "availability model". (Reproduced from Zvelebil 1986, Fig. 3)

might be diverted to nearby Leningrad (now St. Petersburg), potentially resulting in his enforced return to Communist Czechoslovakia.

Major Accomplishments

Marek was part of the small group of scholars who argued that hunter-gatherer lives did not have to be "nasty, brutish, and short," and that in favorable areas like the Baltic coasts, hunter-gatherer populations might be as dense and society as hierarchical as those of early farmers. The "availability model" for the origins of agriculture in the Baltic made the hunter-gatherers active players in the transition to agriculture by defining three phases in the process (Zvelebil and Rowley-Conwy 1984):

- The availability phase: hunter-gatherers are aware of agriculture practiced by neighboring farmers but adopt little or none of it; agriculture produces <5% of food.
- The substitution phase: farming is being adopted and the two ways of life are in competition due to scheduling clashes between farming and foraging; agriculture produces 5–50% of food.
- The consolidation phase: farming matures and spreads into suboptimal parts of the region; agriculture provides >50% of food.

Marek further developed this model 2 years later, in a paper (Zvelebil 1986) from which Fig. 1 is taken. This model was in direct opposition to immigration or "wave of advance" models of the spread of agriculture into Europe, in which the hunter-gatherer population did not even feature. In immigration models, the first appearance of any domesticated species constituted the "Neolithic Revolution," but in the availability model,

Zvelebil, Marek, Fig. 2 Chart of increasing hunter-gatherer population density and its economic outcomes. (Reproduced from Zvelebil 1995, Fig. 2)

revolutionary change occurred only towards the end of the substitution phase and the transition to the consolidation phase.

The existence of lengthy availability phases of a millennium or more in various parts of the Baltic, when the agricultural spread halted, suggested that dense local populations of hunter-gatherers saw no reason to adopt farming. These dense populations were based on their sophisticated use of abundant but highly seasonal resources, which allowed long-term demographic expansion and economic intensification. The way Marek viewed this is shown in Fig. 2 (from Zvelebil 1995): population density (the dotted line) increases inexorably; each time it impacts the regional resource productivity ceiling (the solid line), a new solution is found (the practices on the vertical axis), allowing population density to increase once more. His major reviews of the exploitation of native plant and animal species suggested a degree of local domestication by hunter-gatherers before the advent of Neolithic farming (Zvelebil 1994, 1995).

Marek focused attention on the zone where hunter-gatherers and farmers met. He stressed the importance of connections across the boundary: ceramics, stone axes, and perhaps some agricultural items were documented moving north from the farmers to the hunter-gatherers. Commodities moving south were less easily visible in the archaeological record but might have included forest products such as furs and honey, seal fat, and also amber from the Baltic (Zvelebil 1996, 2006). For a long period this interaction would have been stable and balanced, as shown in Fig. 3 (left). But the longer the frontier lasted, the more disruptive its effects would be on hunter-gatherer society. Prestige items imported from the farmers would lead to competition between hunter-gatherers, disrupting the social fabric. This would lead to the "commercialization" of some hunter-gatherer procurement activities, to obtain

Zvelebil, Marek, Fig. 3 *Left*: model of balanced system of exchange between Ellerbek/Ertebølle hunter-gatherers and LBK/Baalberg/TRB farmers. (Reproduced from Zvelebil 1996, Fig. 18.5. Marek's spellings of place-names were sometimes idiosyncratic!). *Right*: model of a destabilized hunter-gatherer/farmer frontier zone. (Reproduced from Zvelebil 1996, Fig. 18.8)

exportable commodities for exchange with the farmers. Hypergyny – the outmarriage of hunter-gatherer women to farmers and the consequent lack of mates for some male hunter-gatherers – would further destabilize things. Both competition and hypergyny would cause disruption to the hunter-gatherer society and might lead to farmers encroaching upon hunter-gatherer lands, initially to obtain their own forest products but subsequently to settle areas suitable for agriculture (Fig. 3 right).

This is probably the most in-depth consideration of any hunter-gatherer/farmer interaction in Europe. Needless to say, modifications have been suggested to some aspects of the intensification/population growth model (e.g., Rowley-Conwy 2004), but Marek's treatment remains the core study for the Baltic area, standing as something of a model of its kind. It should not be assumed that the Baltic pattern will be replicated everywhere: one attempt to apply it to the Adriatic (Zvelebil and Lillie 2000) has drawn criticism because of the lack of forager-farmer continuity in the region (Biagi and Spataro 2002). But the availability model can be employed as a useful search tool in any area.
